This conceptual structure leaves open the possibility that some of these boxes may contain no substantive constraints. For example, there may be no first-order material demands of commutative justice if any exchange, no matter how lopsided, is morally acceptable so long as it has been performed freely by the exchanging parties without unfair inequalities in bargaining power or information. But this is not a conceptual point, but rather a substantive claim, affirmed by some (especially modern) and denied by other (especially medieval) conceptions of justice.

This complexity can be increased to sixty-four because—perpendicular to the three dimensions in which the character of diverse justice assessments can be differentiated—there is still the distinction between four categories of judicanda (introduced earlier) to which any such justice assessments can be applied: namely, individual and collective actors, their actions and omissions, social rules and institutions, and states of affairs and events.

In some accounts, *international* justice is given as a separate domain that, traditionally, is heavily focused on the use of force and, in particular, on just and unjust causes for going to war (*ius ad bellum*), and on just and unjust ways of fighting a war (*ius in bello*). (In his *Metaphysics of Morals* [pp. 343, 347–349], Kant adds a third theme: the just way of concluding a war so as to lay the foundation for a stable peace [*ius post bellum*]) It seems more appropriate, however, to think of states as one class

of collective actors among others. It may indeed be claimed that states are a special class of actors and that their conduct and relations are subject to distinctive justice requirements. But this is a substantive moral claim that should not be prejudged in the conceptual explication.

A state is understood not merely as a collective actor, but also as a comprehensive system of social rules and institutions enforced in a particular territory. A state can therefore be criticized as unjust not merely on account of its conduct toward or institutional relations with outsiders, but also on account of its internal institutional order—for instance, on account of how it distributes rights and duties, regulates and taxes economic cooperation, and enforces its laws against its members. So understood, states exemplify one kind of institutional scheme among others, whose special status once again should not be prejudged in the conceptual explication.

#### TOWARD A UNIFIED CONCEPTION OF JUSTICE

The preceding sections were meant to sketch the structure of the contemporary concept of justice and thereby to characterize the linguistic consensus that underlies current debates about questions of justice. Even these general thoughts may not be wholly uncontroversial. But they are much less controversial than the thoughts to follow, which are meant to describe plausible elements of a conception of justice. Should these elements be found convincing, they might gradually become elements of a clearer and more unified concept of justice. But they do not now fully accord with the various understandings of this concept that are dominant in contemporary public and academic discussions.

It is possible to begin once more from the question, briefly raised in (1): What is specific about justice, how justice judgments are distinctive within the larger realm of moral judgments; what is being said with the complaint that some *judicandum* is unjust, over and above the claim that this *judicandum* is immoral (morally flawed)? What follows are four hypotheses toward answering this question.

**FIRST HYPOTHESIS: INJUSTICE INVOLVES ABUSE OF MORALITY ITSELF.** Morally flawed *judicanda* are unjust only if they involve an abuse of morality itself—that is, only if they appear with a moral pretension they do not live up to. Unjust is someone who is prepared to violate moral principles she herself likes to appeal to. Unjust is someone who allows his official conduct to be influenced

by bribes even while he pretends to be an impartial judge, umpire, or mediator. Unjust is a beating falsely presented as deserved punishment. And unjust is legislation designed for the benefit of a small minority and yet claimed to impose moral obligations on the oppressed population. In all these cases, the injustice comes about through the false moral claim: Without the pretense of deserved punishment, the beating is wrong but not unjust. Without the claim of moral authority (that compliance is morally required), coercive rules can be wrong, but not unjust.

According to this first hypothesis, then, justice is a part of morality that defends the authority and dignity of morality itself. This would explain the central place justice is thought to occupy within morality. Unjust are only those *judicanda* that do not merely—openly or covertly—violate morality, but also appear under color of morality.

**SECOND HYPOTHESIS: JUSTICE MAY IN PRINCIPLE BE ENFORCED.** A second essential mark of injustice may be that it involves a violation of a right and, more precisely, of a moral right. (Injustice need not violate positive law. To the contrary, because positive law may be unjust or otherwise immoral, conduct it permits or even requires may still be unjust.) Violations of rights are those moral infractions that may in principle be averted through the use or threat of coercive force. The main implication of the second hypothesis therefore is that any injustice may in principle be forcibly averted. Justice may be enforced.

The expression “in principle” flags two qualifications. First, it is not meant that anyone is permitted forcibly to avert any rights violations. In a well-ordered society, for instance, only the police and the courts are permitted to use force in response to rights violations—ordinary citizens may use or threaten force only in urgent emergencies. Second, there is no permission to use force regardless of the morally significant costs of doing so. Defensive force may be grossly disproportionate and therefore impermissible. And efforts forcibly to avert a rights violation may also be impermissible when they carry the risk of triggering much graver violations of the rights of third parties (a point well illustrated in Heinrich von Kleist’s story “Michael Kohlhaas”). That any rights violation may in principle be forcibly averted thus means only that those responsible for it and those profiting from it have no moral right against having this violation blocked by force. Here justice contrasts with other moral qualities. No moral rights are violated by *judicanda* lack-

ing in generosity, civility, charity, humanity, decency, kindness, courtesy, mercy, or beneficence. Enforcing these virtues is wrong in principle and violates moral rights of those against whom they are enforced.

**THIRD HYPOTHESIS: INJUSTICE HARMS IN VIOLATION OF NEGATIVE DUTIES.** Related to the preceding, another essential mark of injustice may be that it always involves a violation of negative duties on the part of those who are responsible for the moral quality of the *judicandum* in question. What is at issue here, roughly speaking, is the traditional distinction between moral infractions that harm recipients and those that merely fail to help them. However this distinction may be made precise, the third hypothesis is simply that a claim of injustice always involves a claim of undue harm.

This hypothesis is related to the second hypothesis insofar as the two distinctions may wholly or largely coincide. That they coincide precisely would mean that people in every case have a right not to be harmed but in no case a right to be helped. Therefore, only harmings may be forcibly averted, refusals of help must not be.

It is doubtful that the two distinctions coincide precisely. Many civil-law countries have “Good Samaritan” laws proscribing failure to render assistance. These statutes presuppose, as seems plausible, that there are cases in which morally mandatory assistance may be compelled through threat of criminal sanctions. Conversely, there may also be harmings that are so trivial that in principle they must not be forcibly averted.

Still, the two distinctions largely coincide, and some moral predicates fall entirely on one side or the other. *Judicanda* lacking in morally required or recommended generosity, civility, charity, humanity, decency, kindness, courtesy, mercy, or beneficence fail to help people without harming them. Such infractions may not be forcibly averted. Any injustice in a *judicandum*, however, does harm people and thus may in principle be forcibly averted.

The last two hypotheses differ in their informative value for the investigation of justice. The second hypothesis is illuminating: something important is learned about justice, if one finds that in principle every injustice may be forcibly averted. The third hypothesis would be similarly informative if it started out with a clear justice-independent notion of harm. The claim would then be that a *judicandum* is unjust only if it harms persons (in this independent sense). But the connection postulated by the third hypothesis can also be taken in the opposite way: Any unjust treatment is to count as a harming. So

understood, this claim would be using a harm-independent notion of injustice to illuminate the notion of harm—rather than the other way around. Still, although the latter definitional sequencing seems more adequate, it is moderated by the need to preserve the core meaning of harm. Coming back to Kant’s example, failure to give a criminal his deserved punishment cannot plausibly be presented as an instance of harming him. If one wants to call such an act of grace unjust (while maintaining the third hypothesis), then one must identify another harmed party—other criminals arbitrarily excluded from the amnesty, perhaps, or future victims of crimes that would not have occurred but for this failure to punish. Given this constraint imposed by the core meaning of harm, the third hypothesis is not then entirely uninformative.

**FOURTH HYPOTHESIS: JUSTICE IS NOT PURELY RECIPIENT-ORIENTED.** The last hypothesis is negative in character. It merely rejects a hypothesis that has come to dominate Anglophone academic discussions of justice. The refutation of this approach eliminates only one of many possibilities and may thus seem to make little progress. But because the rejected approach is so elegant and influential, it is interesting nonetheless to explore how it fails.

The approach to be criticized has developed out of utilitarianism, which holds that the moral assessment of actors, conduct, and social rules should be based solely on each such *judicandum*’s relative impact on the world, and on human happiness in particular.

If such a view is accepted, the ordinary distinctions among moral predicates lose much of their significance. Whatever moral predicate may be used to criticize a rule, action, or person—cowardly, unjust, evil, indecent, and so on—the complaint always boils down to the *judicandum*’s failure to be optimally happiness-promoting. Utilitarians have little use for the received panoply of moral predicates because it ultimately does not matter how a suboptimal *judicandum* is squandering potential human happiness.

Those who reduce the traditional multiplicity of moral defects in this way may simply want to do away with the surplus predicates. Alternatively, they may prefer to redeploy these predicates—using them not (as traditionally) for different defects of the same *judicanda*, but instead for defects in different kinds of *judicanda*. In this way, justice has come to name the specific moral virtue of social rules.

In his famous *A Theory of Justice* (1999 [1971]), John Rawls adopts this redeployment. His theory is focused exclusively on social institutions and, even more narrowly, on a society's basic institutional design. And, presenting justice as the first virtue of social institutions, he recognizes no further moral predicates by means of which such institutions might be subjected to potentially competing moral judgments.

Rawls further follows the utilitarians by adopting a broadly consequentialist mode of moral assessment, and one that focuses specifically on the well-being of individuals. Thus he shares with utilitarianism the purely recipient-oriented mode of moral assessment. The unique characteristic of this approach can be expressed as the assumption that the only information needed in the moral assessment of any *judicandum* is information about its relative impact on persons, that is, information about how persons fare with the *judicandum* as it is versus how they would fare if the *judicandum* were different.

Unlike the utilitarians, Rawls employs the purely recipient-oriented approach on two distinct levels and moreover rejects, on both levels, utilitarian conceptions of well-being as happiness or desire fulfillment. Central to his theory is a criterion ("the two principles") of justice that assesses alternative institutional designs on the basis of the distribution of social primary goods each would produce. The just design is the one that would produce the best feasible distribution among citizens of basic rights and liberties, income and wealth, powers and responsibilities of office, and other social bases of self-respect. This proposed criterion of justice is justified, again in a purely recipient-oriented manner, on the ground that its public adoption would lead to a better fulfillment of citizens' three higher-order interests than the public adoption of any alternative criterion of justice. The argument on this second level is presented in terms of a contractualist thought experiment ("original position") in which representatives of citizens, informed only that their clients have the three higher-order interests but given no further specific information about them, come to agree on a particular public criterion of justice.

Rawls's theory, with its particular assessment standards on the two levels, has received much lively critique. Under the *Equality of What?* label, academics debate whether human well-being should be conceived in terms of happiness, welfare, desire fulfillment, Rawlsian social primary goods, Dworkinian resources, or capabilities à la Sen or Nussbaum. And academics also debate how such well-being information about individuals should be aggregated: Should well-being simply be averaged or

should special weight be given to equality, sufficiency, or the worse off? Yet, beneath all this disagreement, the purely recipient-oriented approach is largely taken for granted in the Anglophone countries.

The fourth hypothesis is that any such purely recipient-oriented conceptions of justice are untenable.

**DEFENSE OF THE FOURTH HYPOTHESIS.** When it comes to actors and their conduct, the fourth hypothesis is—at least outside academic philosophy—hardly controversial. Here any conception of the form "to be just is to promote a good distribution among one's recipients" is bound to be unacceptable because it disregards morally relevant information about how a *judicandum* has its effects. It is widely taken to make a great moral difference whether some conduct brings about the death of an innocent person or merely fails to prevent such a death. The world at large may be worse, perhaps even less just, if two good persons die prematurely than if a single less deserving person dies in their stead. And yet, it is not morally required, nor even permitted, to save the former by killing the latter.

An analogous point applies to social institutions. This is clearest when one reflects on the criminal law. Here Rawls's first priority rule (*A Theory of Justice* 1999 [1971], p. 266) holds that basic liberties may be restricted whenever such restriction, by making the remaining basic liberties more secure, is a gain on balance for the basic liberties of the representative citizen. This claim fits well with his purely recipient-oriented approach as enshrined in the contractualist thought experiment of the original position. But it is inconsistent with the considered judgments his theory was meant to accommodate and to unify. One of the examples Rawls gives (*A Theory of Justice* 1999 [1971], pp. 212–213) involves a strict-liability criminal statute that permits conviction without a showing of *mens rea*. Although it violates citizens' basic liberties, this law is nonetheless said to be permissible as "the lesser of two evils" if it is necessary to block even greater dangers to citizens' basic liberties (a danger of civil war, in his example).

Similar arguments could plausibly be made in regard to other aspects of the criminal law. Constraints on searches, seizures, and interrogations should be relaxed if this would entail, through more effective crime fighting, a net gain for citizen's basic liberties. Standards of evidence ("beyond a reasonable doubt") should be lowered, and less than unanimity be required for a jury conviction, if this would, through increased deterrence and through disabling more repeat offenders, produce a net gain for

citizen's basic liberties. And draconian punishments (e.g., execution) should be imposed for high-elasticity crimes (e.g., drunk driving) if citizens' overall risk of a premature violent death can thereby be reduced.

These theory-produced judgments collide with people's intuitive sense of justice, which is responsive not merely to the magnitudes, probabilities, and distribution of morally significant goods and ills, but also to the attitude social rules manifest and to the causal pathways on which they affect their recipients. Even if these recipients themselves have no reason to care whether burdens falling on them (such as hunger or risks of premature death) are imposed by social rules or merely not averted by them, this difference is nonetheless morally significant. The purely recipient-oriented approach cannot then fulfill Rawls's stated ambition of accommodating and unifying his compatriots' considered judgments.

The reason is that judgments of justice take account not only of the passive perspective of recipients, of citizens as governed by social rules, but also of the active perspective of authors, of citizens as co-responsible for these rules. For citizens as recipients, all threats to their basic liberties are indeed on a par—whether they arise from criminal or crime-fighting activities. But for citizens as co-legislators it makes a considerable difference whether people are roughed up by criminals or by police interrogators, are killed prematurely by a drunk driver or through execution for drunk driving. As co-legislators, people take greater moral responsibility for harms they mandate or authorize through their institutional order than for equal harms they could prevent through it. That some institutional arrangements would be better for citizens as recipients is not sufficient to show that they are morally permitted—let alone required. Purely recipient-oriented conceptions of justice are bound to fail because they systematically ignore the active perspective of those who bear responsibility for a particular *judicandum*.

Plausible justice assessments of social rules must be sensitive to both citizen perspectives. What matters in the moral assessment of social rules is not merely how these rules affect, but how they treat their recipients. The importance of this point extends well beyond the criminal law. A rule under which those suffering from some genetic defect are not entitled to life-saving treatment may be exactly as bad for them as a rule mandating execution for those with certain physical features is for the executed. Though comparable in their relative impact on recipients, these two rules are nonetheless worlds apart in how they treat such recipients.

Once such differences in attitude and causal pathways have been restored their proper moral significance, people may well find that justice is not the only moral virtue of social institutions. If a society's institutional order provides little funding for public health services, more citizens will avoidably die or suffer. And yet, such an order is surely less unjust than one under which equal suffering and deaths are explicitly imposed by the rules, perhaps on members of a certain ethnic or religious minority. In fact, in a poor society with other urgent needs, low funding for public health services may not be unjust at all. And even in an affluent society, such low funding may not be unjust, so long as society helps treat the medical conditions it causes (e.g., through pollution). Still, if the institutional order of an affluent society ignores the plight of citizens with congenital medical conditions, say, it may well be morally flawed in other ways: be ungenerous, mean, or inhumane.

This result supports the fourth hypothesis by showing it to be a step toward a conception of justice that covers all *judicanda* in a unified way: In regard to actors and their conduct people are already familiar with the possibility of actors being beyond reproach in terms of justice and yet morally flawed in other ways.

## JUSTIFICATION OF MORAL PRINCIPLES

See *Moral Principles: Their Justification*

## JUST WAR THEORY

In traditional just war theory there are two basic elements: an account of just cause and an account of just means. Just cause is usually specified as follows:

- (1) There must be substantial aggression.
- (2) Nonbelligerent correctives must be either hopeless or too costly.
- (3) Belligerent correctives must be neither hopeless nor too costly.

Needless to say, the notion of substantial aggression is a bit fuzzy, but it is generally understood to be the type of aggression that violates people's most fundamental rights. To suggest some specific examples of what is and is not substantial aggression, usually the taking of

hostages is regarded as substantial aggression while the nationalization of particular firms owned by foreigners is not so regarded. But even when substantial aggression occurs, frequently nonbelligerent correctives are neither hopeless nor too costly. And even when nonbelligerent correctives are either hopeless or too costly, in order for there to be a just cause, belligerent correctives must be neither hopeless nor too costly.

Traditional just war theory assumes, however, that there are just causes and goes on to specify just means as imposing two requirements:

- (1) Harm to innocents should not be directly intended as an end or a means.
- (2) The harm resulting from the belligerent means should not be disproportionate to the particular defensive objective to be attained.

While the just means conditions apply to each defensive action, the just cause conditions must be met by the conflict as a whole.

It is important to note that these requirements of just cause and just means are not necessarily about war at all. Essentially, they constitute a theory of just defense that can apply to war but can also apply to a wide range of defensive actions short of war.

### THE INTENDED/FORESEEN DISTINCTION

Just war theory presupposes that we can, in practice, distinguish between what is foreseen and what is intended, and some have challenged whether this can be done. So first one needs to address this challenge.

The practical test that is frequently appealed to in order to distinguish between foreseen and intended elements of an action is the Counterfactual Test, according to which two questions are relevant:

- (1) Would you have performed the action if only the good consequences would have resulted and not the evil consequences?
- (2) Would you have performed the action if only the evil consequences resulted and not the good consequences?

If an agent answers “yes” to the first question and “no” to the second, some would conclude that (1) the action is an intended means to the good consequences, (2) the good consequences are an intended end, and (3) the evil consequences are merely foreseen.

But how well does this Counterfactual Test work? Douglas P. Lackey argues that the test gives the wrong result in any case where the “act that produces an evil effect produces a larger good effect” (1987, p. 260). He cites the bombing of Hiroshima, Japan, as an example. That bombing is generally thought to have had two effects: the killing of Japanese civilians and the shortening of World War II. Now suppose we were to asked:

- (1) Would Harry S. Truman have dropped the bomb if only the shortening of the war would have resulted but not the killing of the Japanese civilians?
- (2) Would Truman have dropped the bomb if only the Japanese civilians would have been killed and the war not shortened?

And suppose that the answer to the first question is that Truman would have dropped the bomb if only the shortening of the war would have resulted but not the killing of Japanese civilians, and that the answer to the second question is that Truman would not have dropped the bomb if only the Japanese civilians would have been killed and the war not shortened. Lackey concludes from this that the killing of civilians at Hiroshima, self-evidently a means for shortening the war, is by the Counterfactual Test classified not as a means but as a mere foreseen consequence. On these grounds Lackey rejects the Counterfactual Test as an effective device for distinguishing between the foreseen and the intended consequences of an action.

Unfortunately, this is to reject the Counterfactual Test only because one expects too much from it. It is to expect the test to determine all the following:

- (1) Whether the action is an intended means to the good consequences.
- (2) Whether the good consequences are an intended end of the action.
- (3) Whether the evil consequences are simply foreseen consequences.

In fact, this test is capable of meeting only the first two of these expectations. And the test clearly succeeds in doing this for Lackey’s own example, where the test shows the bombing of Hiroshima to be an intended means to shortening the war, and shortening the war an intended consequence of the action.

To determine whether the evil consequences are simply foreseen, however, an additional test is needed, which can be called the Nonexplanation Test. According to this test the relevant question is: Does the bringing about of

the evil consequences help explain why the agent undertook the action as a means to the good consequences? If the answer is “no,” that is, if the bringing about of the evil consequences does not help explain why the agent undertook the action as a means to the good consequences, the evil consequences are merely foreseen. But if the answer is “yes,” the evil consequences are an intended means to the good consequences.

Of course, there is no guaranteed procedure for arriving at an answer to the Nonexplanation Test. Nevertheless, when we are in doubt concerning whether the evil consequences of an act are simply foreseen, seeking an answer to the Nonexplanation Test will tend to be the best way of reasonably resolving that doubt. For example, when applied to Lackey’s example, the Nonexplanation Test comes up with a “yes,” since the evil consequences in this example do help explain why the bombing was undertaken to shorten the war. For, according to the usual account, Truman ordered the bombing to bring about the civilian deaths, which by their impact on Japanese morale were expected to shorten the war. So, by the Nonexplanation Test, the civilian deaths were an intended means to the good consequences of shortening the war.

Just war theory has been challenged in various ways. Three of the most important are a conventionalist challenge to just means, a collectivist challenge to just means, and a feminist objection to just cause and just means.

### A CONVENTIONALIST CHALLENGE TO JUST MEANS

The criteria of just means have been incorporated to some degree into the military codes of different nations and adopted as international law. George Mavrodes (1984) contends that the criteria of just means ought to be met simply because they have been incorporated into military codes or adopted as international law. Mavrodes arrives at this conclusion largely because he finds the standard attempts to specify the convention-independent basis for condition (2) of just means to be so totally unsuccessful. All such attempts, Mavrodes claims, are based on an identification of innocents with noncombatants. But by any plausible standard of guilt and innocence with moral content, Mavrodes contends, noncombatants can be guilty and combatants innocent. For example, noncombatants who are doing everything in their power to support an unjust war financially would be morally guilty, and combatants who were forced into military service and intended never to fire their weapons at anyone would be morally innocent. Consequently, the guilt-

innocence distinction will not support the combatant-noncombatant distinction.

Hoping to support the combatant-noncombatant distinction, Mavrodes suggests that the distinction might be grounded on a convention to observe it. This would mean that our moral obligation to abide by condition (2) of just means would be a convention-dependent obligation. Nevertheless, Mavrodes does not deny that we have some convention-independent obligations. Our obligation to refrain from wantonly murdering our neighbors is given as an example of a convention-independent obligation, as is our obligation to reduce the pain and death involved in combat. But to refrain from harming noncombatants when harming them would be the most effective way of pursuing a just cause is not included among our convention-independent obligations.

Still, Mavrodes does not claim that our obligation to refrain from harming noncombatants is purely convention-dependent. He allows that, in circumstances in which the convention of refraining from harming noncombatants does not exist, we might still have an obligation to unilaterally refrain from harming noncombatants, provided that our action will help give rise to a convention prohibiting such harm with its associated good consequences. According to Mavrodes, our primary obligation is to maximize good consequences, and this obligation requires that we refrain from harming noncombatants when that will help bring about a convention prohibiting such harm. By contrast, someone who held that our obligation to refrain from harming noncombatants was purely convention-dependent would never recognize an obligation to unilaterally refrain from harming noncombatants. On a purely convention-dependent account, obligations can only be derived from existing conventions; the expected consequences from establishing a particular convention could never ground a purely convention-dependent obligation. But while Mavrodes does not claim that our obligation to refrain from harming noncombatants is purely convention-dependent, he does claim that this obligation generally arises only when there exists a convention prohibiting such harm. According to Mavrodes, the reason for this is that, generally, only when there exists a convention prohibiting harm to noncombatants will our refraining from harming them, while pursuing a just cause, actually maximize good consequences.

But is there no other way to support our obligation to refrain from harming noncombatants? Mavrodes would deny that there is. Consider, however, Mavrodes’s own example of the convention-independent obligation

not to wantonly kill our neighbors. There are at least two ways to understand how this obligation is supported. Some would claim that we ought not to wantonly kill our neighbors because this would not maximize good consequences. This appears to be Mavrodes's view. Others would claim that we ought not to wantonly kill our neighbors, even if doing so would maximize good consequences, simply because it is not reasonable to believe that our neighbors are engaged in an attempt on our lives. Both of these ways of understanding how the obligation is supported account for the convention-independent character of the obligation, but the second approach can also be used to show how our obligation to refrain from harming noncombatants is convention-independent. According to this approach, since it is not reasonable to believe that noncombatants are engaged in an attempt on our lives, we have an obligation to refrain from harming them. So interpreted, our obligation to refrain from harming noncombatants is itself convention-independent, although it will give rise to conventions.

Of course, some may argue that whenever it is not reasonable to believe that persons are engaged in an attempt on our lives, an obligation to refrain from harming such persons will also be supported by the maximization of good consequences. Still, even if this were true, which seems doubtful, all it would show is that there exists a utilitarian or forward-looking justification for a convention-independent obligation to refrain from harming noncombatants; it would not show that such an obligation is a convention-dependent obligation, as Mavrodes claims.

### A COLLECTIVIST CHALLENGE TO JUST MEANS

According to a collectivist challenge to just means, more people should be included under the category of combatants than the standard interpretation of just means allows. Just means, as noted earlier, imposes two requirements:

- (1) Harm to innocents should not be directly intended as an end or a means.
- (2) The harm resulting from the belligerent means should not be disproportionate to the particular defensive objective to be attained.

According to advocates of this challenge to just means, the problem is that the standard interpretation of (1) does not assume that the members of a society are collectively responsible for the actions of their leaders unless they have taken radical steps to oppose or disassociate

themselves from those actions, for example, by engaging in civil disobedience or by emigrating. Of course, those who are unable to take such steps, particularly children, would not be responsible in any case; but for the rest, advocates of this collectivist challenge contend that failure to take the necessary radical steps, when one's leaders are acting aggressively, has the consequence that one is no longer entitled to full protection as a noncombatant. Some of those who press this objection against the just means criteria of just war theory, like Gregory Kavka (1985), contend that the members of a society can be directly threatened with nuclear attack to secure deterrence, and so reject noncombatant immunity, but then deny that carrying out such an attack could ever be morally justified. Others, like James W. Child (1986), reject both noncombatant immunity and proportionality by contending that the members of a society who fail to take the necessary radical steps can be both indirectly threatened and indirectly attacked with what would otherwise be a disproportionate attack.

In response to this collectivist challenge the first thing to note is that people are more responsible for disassociating themselves from the unjust acts of their leaders than they are for opposing those same acts. For there is no general obligation to oppose all unjust acts, even all unjust acts of one's leaders, because this would impose an unreasonable demand on individuals, and we are not morally required to be saints. Nevertheless, there is a general obligation to disassociate oneself from unjust acts and to minimize one's contribution to them, because this is not an unreasonable demand to impose on each of us. Of course, how far one is required to disassociate oneself from the unjust acts of one's leaders depends on how much one is contributing to those actions. If one's contribution is insignificant, as presumably a farmer's or a teacher's would be, only a minimal effort to disassociate oneself would be required, unless one's action could somehow be reasonably expected, in cooperation with the actions of others, to put a stop to the unjust actions of one's leaders. However, if one's contribution is significant, as presumably a soldier's or a munitions worker's would be, a maximal effort at disassociating oneself would be required immediately, unless by delaying one could reasonably expect to put a stop to the unjust actions of one's leaders.

In support of this collectivist challenge to just war theory Child (1986) offers the example of a member of a board of directors of a company that is engaging in the immoral and illegal activity of pouring large quantities of arsenic into the public water supply as a matter of ongo-

ing operations. When the policy is before the board, she votes no but does nothing else. Later, when sued in tort (or charged in crime) with these transgressions of duty, she pleads that she voted no. Child argues that mere formal dissent in this case does almost nothing to relieve her liability, legal or moral.

But while one might agree with Child that in this case the member of the board of directors had at least the responsibility to disassociate herself from the actions of the board by resigning, this does not show that farmers and teachers are similarly responsible for disassociating themselves from the unjust action of their leaders either by engaging in civil disobedience or by emigrating. This is because neither their contributions to the unjust actions of their leaders nor the effect of their disassociation on those unjust actions would typically be significant enough to require such a response.

This is not to deny that some other response (e.g., political protest or remunerations at the end of the war) would not be morally required. However, to meet this collectivist challenge, it suffices to show that not just any contribution to the unjust actions of one's leaders renders the contributor subject to attack or threat of attack; one's contribution must be significant enough to morally justify such a response.

### A FEMINIST CHALLENGE TO JUST CAUSE AND JUST MEANS

A formidable challenge to both the just cause and just means criteria of just war theory comes from feminism. According to the feminist challenge to just war theory, sexism and militarism are inextricably linked in society. They are linked, according to Betty Reardon (1985), because sexism is essentially a prejudice against all manifestations of the feminine, and militarism is a policy of excessive military preparedness and eagerness to go to war that is rooted in a view of human nature as limited to masculine characteristics. Seen from a militarist perspective, other nations are competitive, aggressive, and averse to cooperation, the same traits that tend to be fostered primarily in men in a sexist society. By contrast, the traits of openness, cooperativeness, and nurturance that promote peaceful solutions to conflicts tend to be fostered primarily in women, who are then effectively excluded from positions of power and decision making in a sexist society. Consequently, if people are to rid society of militarism, Reardon argues, they need to rid society of sexism as well.

But even granting that sexism and militarism are inextricably linked in society in just the way Reardon maintains, how does this effect the validity of just war theory? As just war theory expresses the values of proportionality and respect for the rights of innocents, how can it be linked to militarism and sexism? The answer is that the linkage is practical rather than theoretical. If the leaders in militarist-sexist society have been socialized to be competitive, aggressive, and averse to cooperation, then they will tend to misapply just war theory when making military decisions. This represents an important practical challenge to just war theory. And the only way of meeting this challenge seems to be to rid society of its sexist and militarist attitudes and practices so as to increase the chances that just war theory will be correctly applied in the future.

Of course, still other challenges could be raised to just war theory but, in large measure, just war theory has stood the test of time. Moreover, if the theory can be reconciled with the most morally defensible form of pacifism, such that the only wars and large-scale conflicts that definitely satisfy the requirements of just war theory are the only wars and large-scale conflicts to which antiwar pacifists cannot reasonably object, then it is really hard to see how the theory could be displaced.

## KABBALAH

Kabbalah (literally “tradition”) is used both as a general name for Jewish mysticism and as the specific designation for its major medieval variety. Mystical awareness is to be found in the biblical and rabbinic tradition and had literary expression in some of the prophetic writings, psalms, and apocalypses. More characteristically, however, what is referred to as Kabbalah is a type of occult theosophical formulation of the doctrines of the Jewish religion, particularly those concerned with creation, revelation, and redemption. This occult system structures and, in part, fossilizes individual intuitions of divine reality in terms of the culture in which it arose. Typically, the purpose of the complicated structuring of these formulated intuitions is to supply a focus in contemplation by which the Kabbalist can recover the untarnished brightness of direct mystical awareness.

Besides the sources of Kabbalah in the doctrines and literature of the Jewish tradition, a wide variety of other sources has been noted, which have introduced elements from the various cultures with which the Jewish people have come in contact in their dispersion. Among these influences should be included some Persian elements, both Parsi and Zoroastrian, and Neo-Platonic and Neo-

Pythagorean elements which entered during the Hellenistic period; Christian influences and Gnostic themes added at a somewhat later time; and borrowings from Muslim sectarianism after the emergence of Islam. This mixture of elements explains the difficulty that scholars have found in disentangling the sources of Kabbalah. It should be said, however, that the pursuit of sources has less relevance here than it may have for other subjects, because what is essential is not the materials out of which the Kabbalistic theosophical system was created, but rather the use that was made of the materials.

### MAJOR DOCTRINES

**CREATION.** All Jewish mysticism has seen the need for reinterpretation of the literal account of creation given in the book of Genesis. As it stands, the account does not sufficiently emphasize the transcendence of God. God is too close to humankind and the world to be the Supreme Mystery that the mystical temper insists He must be. The reinterpretation has generally taken form as a demiurgic theory. In such a theory, God Himself, the Boundless, the Infinite, the Transcendent, did not perform the material act of creating the world. This was the work of a lesser spirit, or demiurge, who was brought into existence by God in order to do this specific job. As the conception of

God's transcendence developed, one demiurge seemed insufficient to express the sense of awesome distance between divinity and the material world. The remoteness of God from the world was heightened, therefore, by adding other intermediaries and thus forming a chain from God to matter whose links were of increasing materiality.

A second problem in the biblical account of creation concerns matter. If we accept God as infinite, all must be contained in Him. Where, then, is there a place for matter outside of God? This issue was finally resolved by a theory that combined the idea of God's voluntary self-contraction with the concept of emanation. In this account, God, prior to creation, was actually infinite. To make room for creation, however, He voluntarily contracted or limited Himself. Some excess of spiritual substance overflowed into the space from which God had removed Himself, and this excess, or emanation, provided both the demiurgic intermediaries described above and the matter out of which the world was created. Because all substance is thus ultimately an overflowing of God's substance, Kabbalah is a pantheistic doctrine. The completed series of emanations served the additional purpose of providing the road by which humanity's aspiring spirit might reach the heights of divinity; thus, it served both as the mechanism of creation and as the "itinerary of the mind to God" (to borrow an expression from St. Bonaventure).

**REVELATION.** After the first destruction of the Temple at Jerusalem, and even more after its second destruction, the Scriptures served as a focus for the religious devotion of the Jews. Their state was no more; their cultus was no more; all that was left to them was their belief in God and His Word. For the continuance of the Jewish religion, it came to seem necessary that not only the content of revelation, but even its physical form, should be considered sacrosanct and unchangeable. In all types of Judaism this regard for the letter of Scripture made necessary the development of exegetic techniques for raising the level of significance of much that is trivial in the Scriptures. For the mystics the problem was particularly difficult, because the level on which they had to interpret revelation to make it serve their purpose was highly symbolical. To make this reinterpretation possible, the Kabbalists developed letter and number symbolisms of great variety and complexity.

**REDEMPTION.** The Kabbalists maintained and even intensified the traditional Jewish view of redemption. In the Kabbalistic view salvation of the individual was little

considered; it entered only as a means to the greater end of the salvation of humankind. This would come about through the agency of a Messiah of the Davidic line, who would lead the Jews in triumph to the Holy Land and inaugurate a reign of truth, justice, and mercy. The ideal of salvation is thus the establishment of an earthly paradise of human life, raised to its highest humanity. Other elements clouded this doctrine at various times in the history of mystical Messianism. For example, in the sixteenth century Isaac Luria introduced the idea that this regeneration could not take place until all preexisting souls had satisfactorily completed their earthly existence and that, since some souls were too weak to go unaided through life to perfection, other superior souls might coexist with them in one body to ensure their success. Although Luria's doctrine of transmigration found followers, it was exceptional rather than typical; in general, the Kabbalistic view of redemption was an extreme form of traditional Messianism. Attempts to calculate the exact date of the coming of the Messiah were widespread; the coincidence of various calculations in fixing on dates close to each other was sufficient to start a wave of Messianic movements and even to touch off a major explosion like the widespread impassioned support of Sabbatai Zevi, the so-called Messiah of Ismir (1626–1676).

## HISTORICAL EXPRESSIONS

While a number of smaller groups, such as the Essenes of Palestine, the Therapeutae of whom Philo wrote, and the eighth-century Persian "Men of the Caves" whom the tenth-century Karaite historian Joseph ben Jacob al-Kirkisani described, maintained views similar in part to those that have been presented, these groups do not lie in the mainstream of Jewish mysticism. The main development is rather to be traced from the Jewish Gnosticism of the first millennium of the common era, with its concentration on the glory of God as manifested in His throne, supposedly located in the innermost of seven heavenly mansions, into the parallel forms of the medieval European developments of the Kabbalah—the practical, ethical, and sometimes magical mysticism of the German Jews and the speculative mysticism of the French and Spanish Jews. Thence the movement became enmeshed in the morbidity of seventeenth-century Messianism, before the two strains of mystical speculation and socioethical piety were reunited, in eastern Europe, in the still-flourishing movement of Hasidism.

The German pietist movement developed during the century between 1150 and 1250. Its chief formulators were Samuel the Hasid (fl. 1150), his son Judah the Hasid

(d. 1217), and a relative, Eleazar of Worms (fl. 1220). The chief literary expression of the movement is the *Book of the Pious* (Hebrew, *Sefer Hasidim*), a collection of the literary remains of the three founders, with special emphasis on Judah the Hasid, whose character and influence recall those of his Christian contemporary, St. Francis of Assisi, and, perhaps, remind one also of Paracelsus, who lived in the sixteenth century and who also combined genuine piety with magic. In addition to its concern with the doctrinal elements that have already been discussed as characteristic of all forms of Jewish mysticism, German Hasidism defined an ideal human type and a way of life—devoutness, rather than learning or traditionalism. The three chief elements in this devoutness were mental serenity, ascetic renunciation, and extreme altruism, leading to heights of devotion in which true fear of God and love of God became one. At these heights, the Hasid was thought to achieve a creative power of a magical nature.

In southern France, at the beginning of the thirteenth century, a more speculative Kabbalistic development began, under the sponsorship of Isaac the Blind (fl. 1200) and his disciples Ezra and Azariel. Their chief concern was the elaboration of emanation theory; they also suggested a doctrine of metempsychosis, although they did not develop it fully. In Spain, Abraham ben Samuel Abulafia (1240–c. 1292) combined this speculation with the development of number and letter symbolism and thus became one of the central figures in the development of Kabbalah. His disciple, Joseph ben Abraham Gikatilia (c. 1247–1305), presented both the techniques for symbolic interpretation and the doctrine of the ten emanations (Hebrew, *sephiroth*) in systematically interrelated form. About 1290 the Spanish Kabbalist Moses ben Shemtob de Leon (d. 1305) produced the work that, for many, represents the Kabbalah in its entirety: the lush compendium of esoteric doctrines in the form of a commentary on the Pentateuch known as *The Book of Splendor* (Hebrew, *Sefer Ha-Zohar*). From the time of its composition, this work has been the chief source of inspiration for later Jewish mystics and for Jewish mysticism. Of later Kabbalistic leaders, two in particular should be mentioned: Moses ben Jacob Cordovero (1522–1570), whose book, *A Garden of Pomegranates* (Hebrew, *Pardes Rimmonim*), is the most systematic and philosophical exposition of the doctrines of the Kabbalah up to his time; and his pupil, Isaac Luria (1534–1572), who left no written legacy, but whose disciples have made it clear that he developed the theosophic doctrines of creation and redemption far beyond his predecessors.

There are still Kabbalistic groups in existence, chiefly in Israel, but they are for the most part outgrowths of eighteenth-century Polish Hasidism, a movement akin to, though by no means identical with, earlier German pietism. Among major Jewish thinkers of the twentieth century, the chief rabbi of Jerusalem, Abraham Isaac Kook (1865–1935), approached most closely the spirit of the Kabbalah in his mystical awareness of the Messianic role of the Jewish people and in his Lurianic and Hasidic stress on the spark of holiness that is veiled by the material shell of things perceived by the senses. Martin Buber, whose reinterpretations of the Hasidic view of life are profound and suggestive, may also be named here and, among younger thinkers, Abraham Joshua Heschel, whose thought has clear kinship with Hasidic social ethics.

## Bibliography

### TEXTS

Of the primary Kabbalistic literature, only the chief sections of the Zohar are available, in an English translation by Harry Sperling, Maurice Simon, and Paul P. Levertoff. 5 vols. (London: Soncino Press, 1931–1934). Other segments of the Zohar in inferior translations are included in S. L. MacGregor Mathers, *The Kabbalah Unveiled* (London, 1887). A theosophized version of *Sefer Yetzirah* is Knut Stenring, *The Book of Formation* (London, 1923). The Hebrew texts have not been critically edited.

Among recent writers of a mystical bent, the works of Martin Buber are readily available in English translations. None of Abraham Isaac Kook's works have been translated; however, there are good discussions of his life and thought in Jacob Agus, *Banner of Jerusalem* (New York: Bloch, 1946) and Isidore Epstein, *Abraham Kook, His Life and Works* (London, 1951). A. J. Heschel is best represented by *God in Search of Man: A Philosophy of Judaism*. (New York: Farrar Straus, 1955).

*The Story of Jewish Philosophy* (New York: Random House, 1962).

J. L. Blau (1967)

## KABBALAH [ADDENDUM]

Medieval Jewish philosophy contributed considerably to the mystical branch of Judaism known as Kabbalah. This movement is generally regarded as having its origins in twelfth and thirteenth-century Provence in the midrashically styled *Bahir* (*Book of Enlightenment*). Some, however, consider the much earlier *Sefer Yetzirah* (*Book of Formation*)—from the third through the seventh centuries—to be the earliest work of Kabbalah.

Chief among the philosophers who influenced concepts within Kabbalah were those who thrived in the Muslim cultures of Babylon (Iraq) and Spain. An example is Saadya Gaon (882–942), head of the Babylonian Yeshivah (religious academy) of Pumbedita. Although Saadya was a rationalist philosopher, he nevertheless published a detailed commentary on *Sefer Yetzirah*. In addition, he posited an intermediary between God and creation, known as the *kavod* or “glory.” It is possible that this concept was influenced by the Karaite thinker, Benjamin al-Nahawandi (830–860), and that both were influenced by the Muslim *kalam*ic (theological) view of the “creative word” of God. Contextually, the idea of the *kavod* is less likely to have been influenced by Christian ideas of the *logos*. The concept of an intermediary between God and creation influenced the seminal idea of the *sefirot* (emanations from the Divine), as developed in all major kabbalistic works.

Abraham ibn Ezra (1089–1164) was born in Muslim Tudela, northern Spain, but lived to see both his own birthplace and other major Spanish cities taken by Christian forces before he was thirty. At fifty he left Spain and traveled through northern Christian Europe, dying in a pogrom in London in 1164. Through his travels, he influenced kabbalistic thought in Ashkenazi and Christian domiciles at both a theoretical and practical level. For example, Ibn Ezra’s complex attitude to the preexistence of “matter” impacted on circles in Provence, out of which the foundations for the *Bahir* emerged. The problem of “matter,” which had not been widely discussed in works of popular Jewish biblical exegesis before Ibn Ezra, played a seminal part in kabbalistic thinking, both in relation to the *sefirot* and also in discussions about the origins and role of evil in the universe. This is particularly true of the

sixteenth-century Lurianic Kabbalah of Sfat, northern Israel.

In some ways an even bolder innovation on Ibn Ezra’s part was his emphasis on the importance of the *mitzvot* (religious commandments) that, when practiced correctly, could affect the deity. This theory influenced theurgical Kabbalah. It was instrumental in lending a psychological dimension to the practice of Kabbalah, in which human beings could be regarded as influencing the deity by means of the *sefirot*.

It is therefore not completely accurate to view Kabbalah solely as a movement (or series of movements) that emerges during certain tragic times of Jewish history. It is more accurate to see it as being embedded at the heart of the Jewish religion, with biblical and rabbinic antecedents. Kabbalah has also been compared to mystical traditions in other religions, notably Sufism, in which emphasis is placed on experience of the Divine. This approach has paralleled neuroscientific interest in the field of consciousness studies. Lastly, developments in the study of language and linguistics have led to emphasis on the importance of the “text” and letter mysticism in Kabbalah. Interest in Kabbalah may thus be summarized as historical, philosophical, psychological, linguistic, and experiential, but as being grounded in the same intellectual milieu as more conventional Jewish genres.

## KAFKA, FRANZ (1883–1924)

Franz Kafka, the German author, was the son of a Jewish businessman who had been a peddler in southern Bohemia. The family was German-speaking. Kafka studied law at the German University of Prague and at Munich and became an official of a workers' accident insurance company. He began writing in 1907 but by his own choice published little. About that time he contracted tuberculosis and for some years lived in various sanatoriums. His two engagements ended unhappily. In 1923 he moved to Berlin, where, living with a girl who was in charge of a Jewish orphanage, he achieved what happiness he was to know. He died of a tubercular infection of the larynx in a nursing home at Kierling, near Vienna.

The central experience of Kafka's life, it seems, was a manifold alienation—as a speaker of German in a Czech city, as a Jew among German and Czech Gentiles in a period of ardent nationalism, as a man full of doubts and an unquenched thirst for faith among conventional “liberal” Jews, as a born writer among people with business interests, as a sick man among the healthy, and as a timid and neurasthenic lover in exacting erotic relationships.

Kafka's narrative art is at once immensely original, prophetic, and fragmentary—hence the large number of mutually exclusive interpretations it has received. Several elements of his prose were the stock in trade of the minor literature of his day. His language is unemphatic and prosy and occasionally contains Prague-German provincialisms; some of the subjects of his stories belong to the horror literature of the turn of the twentieth century; he shared the modern interest in psychological motivation; and he often used the smaller prose genres cultivated by his contemporaries in Prague and Vienna. But the use Kafka made of these elements is startlingly original, and the compelling gnostic vision of the world that is fash-

ioned from them has become one of the major literary and intellectual influences of our age. In Kafka's work the existentialists' conceptions of absurdity and dread are fully explored. Unlike the later existentialists, he did not derive a positive value from these modes of experience; the value of his writings lies in the intense lucidity of the exploration.

It is obvious from the very titles of many of Kafka's stories—*The Trial*, “The Judgment,” “Before the Law,” “The Penal Settlement”—that his work is informed by a strong legalistic strain, possibly derived from his Jewish heritage but then secularized. In the famous “Letter to His Father” (1919) he recounted a certain childhood episode that violated his sense of justice. Characteristically, its terror for him lay in his inability to connect the trivial “crime” with the monstrous punishment he received.

The novel *The Trial*, begun in 1914 and published by Kafka's friend Max Brod in 1925, at once challenges and refines our conventional ways of connecting causes and effects through the story of a young man, Josef K, who one day wakes up in his lodgings to find himself arrested without knowing what wrong he has done. He makes various attempts to justify himself against the enigmatic accusation and to influence a number of people who he believes may effect his acquittal. Although offered a chance of repudiating the jurisdiction of the court that is concerned with his case, he ends up by being marched off to his execution, to die “like a dog.”

The question What has Josef K done? receives a number of detailed answers, the total effect of which is to undermine the reader's notion of guilt. Josef K has lived the unremarkable life of an average young man, a bank clerk. Since in his “ordinary” life he always based his relations with other people on asserting what he believed were his “rights” in this or that situation, it is consistent with his character that he should seek to justify himself before the Law. The only thing he knows about that Law (and the all but unattainable authority behind it) is that it is powerful, whereas he is weak. According to the “inescapable logic” of the world, he must therefore be outside the Law and thus, in some sense, guilty. With his every move the not wholly irrational sense of guilt drags more violently at his soul. At first, this sense is no more than an uneasy “They are sure to have something on me,” but gradually it is magnified by all the actions, in themselves trivial, which constitute “normal” behavior in our world, coupled with Josef K's inability to live “outside the Law,” which for Kafka amounted to consciousness itself. Simplifying the subtly involuted and complex texture of the novel, we may conclude that “minor guilt + situation

of weakness + self-justification = major sense of guilt,” which is tantamount to saying that Kafka’s dialectical ingenuity is expended on making convincing the equation “[subjective] sense of guilt = [objective] guilt.”

Similar dialectical devices are used in the second major work, the unfinished novel *The Castle* (1921–1922, published 1926). K, a land surveyor, has been called to a village that is governed by an authority that resides in a nearby castle. The village and its inhabitants are described only as they are related to K and to his attempts to justify his presence there. His commission, the authority on whose behalf he is to perform it, its relation to himself and to the villagers, the extent of its power, and the morality of its commands—all these are not so much vague as complexly contradictory. (Kafka was prophetically describing the anonymous, muffled workings of a totalitarian ministry as they affect the helpless victim, but since his style is that of an “objective” report, he allowed himself no expressions of pity.) Every assurance that K receives is thrown into doubt either by an oblique contradiction or by K’s own unnerved (and, to the reader, unnerving) insistence on exploring its possible ambiguities.

Again, the novel elaborates a vicious circle. K uses the people he meets in order to wrest from them hints or indications about his task and status but because he lacks the assurance of a clearly defined status and task, he is an outsider and thus in a position of weakness. He is therefore bound to construe all these hints as hostile and thus distrust them. K does not have enough strength to break the spell that the Castle (like the court in *The Trial*) seems to be casting over him, for he looks to it as the place that, in justifying him, will give him strength. And, to keep alive K’s torments of uncertainty, the Castle need do little more than send an occasional hint of a possible way of deliverance.

Leaving aside the various Freudian, Marxist, and Christian interpretations that Kafka’s work has received, its fragmentary nature points to a fundamental hiatus. His heroes’ desolate quests for justice, recognition, and acceptance by the world are meaningful to us because they invoke our sense of pity and justice, whereas the matter-of-fact ways in which these quests are presented invite us to accept cruelty and injustice as though they were necessary and self-evident modes of life. Thus, the meaningfulness of the quests is impaired. Kafka’s writings are indeed prophetic intimations of the logic of the concentration camps; the monstrous insinuation inherent in his prophecies is that the exterminator is not wholly in the wrong, that his hold over his victim is something

more than a matter of superior might, for the victim cooperates in his own destruction.

## Bibliography

### WORKS BY KAFKA

Most of Kafka’s writings were published posthumously and against his express wishes by his friend Max Brod. The complete edition is *Werke* (Frankfurt, 1952–). The “definitive” English edition, published in London, includes *The Trial*, translated by Willa Muir and Edwin Muir (1945); Kafka’s *Diaries*, 2 vols., translated by J. Kresh, M. Greenberg, and H. Arendt (1948–1949); *America*, translated by Willa Muir and Edwin Muir (1949); *In the Penal Settlement: Tales and Short Prose Works*, translated by Willa Muir and Edwin Muir (1949); *The Castle*, translated by Willa Muir and Edwin Muir (1953); *Wedding Preparations in the Country and Other Posthumous Prose Writings*, translated by Ernst Kaiser and Eithne Wilkins (1954); and *Description of a Struggle and The Great Wall of China*, translated by Willa Muir and Edwin Muir and Tania Stern and James Stern (1960). See also Kafka’s *Letters to Milena* (Jesenská), translated by Tania Stern and James Stern (London, 1953), and G. Janouch’s *Conversations with Kafka* (New York, 1953).

### WORKS ON KAFKA

Three biographical studies are available: Max Brod, *Franz Kafka: Eine Biographie* (Frankfurt, 1937), translated as *The Biography of Franz Kafka* (London: Secker and Warburg, 1947); K. Wagenbach, *Franz Kafka: Eine Biographie seiner Jugend, 1883–1912* (Bern: Francke, 1958); and P. Eisner, *Franz Kafka and Prague* (New York: Arts, 1950).

For critical works on Kafka see G. Anders, *Franz Kafka* (London: Bowes and Bowes, 1960); Ronald D. Gray, ed., *Kafka: A Collection of Critical Essays* (Englewood Cliffs, NJ: Prentice-Hall, 1962), which has important contributions by Albert Camus and E. Heller; and Heinz Politzer, *Franz Kafka: Parable and Paradox* (Ithaca, NY: Cornell University Press, 1962).

## KAIBARA EKKEN

(1630–1714)

Kaibara Ekken, or Ekiken, a Japanese Confucianist influential in popularizing Confucian ethics among ordinary people, was born in Fukuoka. The son of a physician, he became a doctor himself, then left medicine to become a Zhu Xi neo-Confucianist. His teachers in Kyoto were Kinoshita Junan (1621–1698) and Yamazaki Ansai. At thirty-nine Kaibara returned to Fukuoka, where he spent the rest of his life in the service of the Kuroda fief. Blessed with an extraordinary capacity for work but little originality, he wrote on many subjects. He became an important botanist with the issuing of separate books on the vegetables, the flora, and the medicinal herbs of Japan. His books on education were pioneering works in pedagogy; *Onna daigaku* (The great learning for women), the standard book on women's ethics in the Tokugawa era, is attributed variously to him and to his well-educated wife. His books were a great success. Unlike most Confucianists, who wrote in Chinese, he wrote in Japanese; furthermore, his teaching was highly practical, applying Confucian morality to everyday life. His pedagogical ideas were not equalitarian (he assigned to women the role of mere submissiveness and obedience to their husbands), and his botanical studies were not at all scientific in the modern sense, but he played an important role in spreading education.

Kaibara's philosophical importance today rests on his *Taigiroku* (The great doubt), in which he aired his dissent with the official doctrine of the Zhu Xi school. Kaibara was also critical of the "ancient learning" school of Confucianism and its scholars Itō Jinsai and Ogyū Sorai, and of the Wang Yangming school, the rival of Zhu Xi. Kaibara disagreed with Zhu Xi Confucianism in his elevation of *ki*, the material force, over *ri*, the principle immanent in all things. For him *ki* is the "great limit" or the "ultimate" and is an all-pervading life force. Kaibara does not distinguish the original form of human nature from its acquired form; contrary to Zhu Xi, he is an optimist in his view of man and of the natural world. His cosmology is characterized by cosmic love that embraces all men, born as they are of heaven and earth. Man's indebtedness to nature is limitless, and for him the Confucian virtue of *jen*, "humaneness," comes close to being a religious benevolence, first toward nature and then toward men. His practical bent, however, makes it difficult to clarify his position, which seems to be one of eclectic doubt rather than critical inquiry. In administrative matters Kaibara opposed imitating Chinese ways; rather he was an ardent patriot, loyal in support of the emperor.

## KALON

*Kalon*: the neuter of the Greek adjective *kalos*, beautiful, fine, also admirable, noble; accompanied by the definite article (*to kalon*), for example, *the* beautiful (or beauty). In Greek culture, what is *kalon* is typically the object of *erōs*, passionate or romantic love, and in (male-dominated) literature (and art), the term is predominantly applied to males around the age of puberty. Plato appropriates the *kalon* (along with the good and the just) as a key object for human striving and understanding in general, discovering in it, along with the good, one of the properties of the universe and of existence; *erōs* itself, in Plato, is transformed from a species of love into love or desire *tout court*, for whatever is truly desirable—and good (for the human agent). See especially his *Symposium*, *Phaedrus* (*Hippias Major*, possibly not by Plato, represents an unsuccessful attempt to define the *kalon*). The truly beautiful, or fine, is identical with the truly good, and also with the truly pleasant, as it is for Aristotle (*Eudemian Ethics* I.1, 1214a1–8). The Aristotelian good man acts "for the sake of the fine (*to kalon*)" (*Nicomachean Ethics* IV.2, 1122b6–7), an idea which is sometimes used as a basis for attributing to Aristotle a quasi-Kantian view of the ideal agent as acting *morally*, even—if occasion arises—*altruistically*, as opposed to acting out of a concern for his or her own good or pleasure. Against this, we need to take account of Aristotle's treatment of his good person as a *self-lover*, someone who seeks a disproportionate share of *the fine* for himself or herself (*NE* IX.8, 1169a35–b1), though he or she may willingly concede his or her share to a friend (*NE* IX.8, 1169a32–34). This is consistent with Aristotle's wanting

to treat the fine (or the admirable) as itself part—the most important part—of the human good; and indeed, he ultimately seems to recognize only two objects of desire, the good and the pleasant (*NE VIII.2*, 1155b18–21; cf. e.g. *EE VII.2*, 1235b18–23). In this context *the pleasant* will include only those pleasures that are not *fine* and good. For this move we may compare Plato's *Gorgias* (474C–475D), where Socrates actually reduces *fine* to good, *pleasant*, or *both*. Later Greek philosophy trades on, while sometimes modifying, this complex of ideas, which also forms the basis for the analysis of beauty in literature or in the visual arts.

## KANT, IMMANUEL

(1724–1804)

Immanuel Kant, the propounder of the critical philosophy, was born at Königsberg in East Prussia; he was the son of a saddler and, according to his own account, the grandson of an emigrant from Scotland. He was educated at the local high school, the Collegium Fridericianum,

and then at the University of Königsberg, where he had the good fortune to encounter a first-class teacher in the philosopher Martin Knutzen. After leaving the university, about 1746, Kant was employed for a few years as a tutor in a number of families in different parts of East Prussia. He kept up his studies during this period and in 1755 was able to take his master's degree at Königsberg and to begin teaching in the university as a *Privatdozent*. He taught a wide variety of subjects, including physics, mathematics, and physical geography as well as philosophy, but nevertheless remained poor for many years. It was not until 1770, when he was appointed to the chair of logic and metaphysics at Königsberg, that his financial stringencies were eased.

Kant's first book, *Gedanken von der wahren Schätzung der lebendigen Kräfte* (Thoughts on the True Estimation of Living Forces), was published as early as 1747 (Königsberg), and between 1754 and 1770 he produced an impressive stream of essays and treatises. His earlier works are primarily contributions to natural science or natural philosophy, the most notable being his *General History of Nature and Theory of the Heavens* of 1755; it was not until after 1760 that philosophical interests in the modern sense became dominant in his mind. Kant's publications had already won him a considerable reputation in German learned circles by the time he obtained his professorship. The ten years following his appointment form a period of literary silence during which Kant was engaged in preparing his magnum opus, the *Critique of Pure Reason*. The appearance of the *Critique* was eagerly awaited by Kant's friends and philosophical colleagues, but when it at last came out in 1781 the general reaction was more bewilderment than admiration. Kant tried to remove misunderstandings by restating the main argument in the *Prolegomena to Every Future Metaphysics* of 1783 and by rewriting some of the central sections of the *Critique* for a second edition in 1787. At the same time he continued, with most remarkable energy for a man of his years, the elaboration of the rest of his system. By 1790 the *Critique of Practical Reason* and the *Critique of Judgment* were in print, and of the major treatises only *Religion within the Bounds of Mere Reason* (1793) and *Metaphysic of Morals* (1797) had still to appear. Kant then enjoyed a tremendous reputation throughout Germany and was beginning to be known, though scarcely to be understood, in other European countries. In his declining years, however, he suffered the mortification of seeing some of the ablest young philosophers in his own country, among them Johann Gottlieb Fichte, Friedrich von Schelling, and J. S. Beck, proclaim that he had not really understood his own philosophy and

propose to remedy the deficiency by producing “transcendental” systems of their own. There is reason to believe that the work on which Kant was engaged in the last years of his life was intended as a counterblast to such critics. But Kant was not able to complete it before his death, and all that remains of it are the fragments gathered together under the title *Opus Postumum*.

Kant’s outer life was almost entirely uneventful. He never married. The one occasion on which he might have become politically prominent was in 1794 when, after the appearance of his book on religion, the Prussian king asked him not to publish further on a topic on which his views were causing alarm to the orthodox. But Kant duly promised, and no scandal ensued. For the rest, he fulfilled the duties of his professorship and took his turn as rector of the university; dined regularly with his friends; admired Jean-Jacques Rousseau and the French Revolution from afar; conversed eagerly with travelers who brought him news of a wider world he never saw himself. Never very robust in body, he carefully conserved his physical resources and was in good health until a relatively short time before his death. He was nearly eighty when he died.

#### CHARACTER OF KANT’S PHILOSOPHICAL WORK

Kant was the first of the major philosophers of modern times to spend his life as a professional teacher of the subject. He was required by university regulation to base his philosophy lectures on particular texts, and he used for this purpose not the works of such major thinkers as René Descartes and John Locke, but the handbooks of his professorial predecessors, notably Christian Wolff, Alexander Gottlieb Baumgarten, and G. F. Meier. Wolff and Baumgarten had dressed out the philosophy of Gottfried Wilhelm Leibniz in what they took to be decent academic garb, presenting Leibniz’ thoughts in the form of a system and with an air of finality foreign to the original; Meier did the same for the doctrines of formal logic. Their example had a near-fatal effect on Kant, for he too thought that philosophy must be thorough if it is to be academically respectable—meaning, among other things, technical and schematic.

In the *Critique of Pure Reason* Kant set out his theories in what he later called progressive order, starting from what was logically first and working forward to familiar facts; in that work he also employed an elaborate terminology of his own and an apparatus of “parts,” “divisions,” and “books” whose titles are alarming and whose appropriateness to the subject matter is not immediately

obvious. It is not surprising that his first readers were unable to discover what the work as a whole was about. The *Critique of Practical Reason* and the *Critique of Judgment* were still more pedantic in form, since in them Kant persisted with much of the formal framework already used in the *Critique of Pure Reason*, in each case proceeding from a part labeled “Analytic” to another labeled “Dialectic,” uncovering one or more “antinomies” in dealing with the dialectic, and ending with an untidy appendix irrelevantly titled “Doctrine of Method.” The fact that Kant was already an old man when he composed these works doubtless explains his attachment to what some commentators have called his architectonic; it is a major obstacle to the proper grasp and unprejudiced evaluation of his ideas. Yet, as passages in his ethical writings in particular show, Kant was capable of expounding his thoughts with clarity, even with eloquence. He was not by nature a bad writer, but he accepted uncritically the scholastic manner cultivated by his fellow professors.

The first task in reading Kant is thus to cut through the formal academic dress in which he clothes his opinions. When this is done, what emerges is not a provincial pedant like Wolff or Baumgarten, but a person of remarkable intellectual and moral stature. Kant’s knowledge of the major European philosophers was often no more than superficial, and his estimate of the work of some of his own contemporaries was certainly overgenerous. But he had, for all that, a sure sense of what was intellectually important at the time; he alone among the eighteenth-century philosophers at once appreciated the greatness of Isaac Newton and was fully aware of the challenge for ethics Newton’s work presented once its seemingly deterministic implications were understood. To sum up Kant’s mature philosophy in a single formula: He wished to insist on the authority of science and yet preserve the autonomy of morals. To achieve this result was a gigantic task, involving consideration of the whole question of the possibility of metaphysics as well as the construction of a theory of scientific knowledge and the elaboration of an ethical system.

Nor was Kant one to be content with mere generalities; he sought to work out his position in detail, with many specific arguments, as well as to state a general case. But the obscurities of his language combine with the extent of his intellectual ambitions to prevent the average reader from grasping precisely what Kant was after; individual points are picked up, but the shape of the whole is not discerned. Yet to be fair to Kant the reader must see the individual views in the wide setting in which Kant saw them himself. To estimate their philosophical value with-

out taking account of their position in the Kantian system, as many critics have tried to do, is quite indefensible.

### PRECITICAL WRITINGS

Kant's philosophical career is commonly divided into two periods, that before 1770, usually referred to as "precritical," and that after 1770, usually referred to as "critical." The word *critical* comes from Kant's own description of his mature philosophy as a form of "critical idealism," an idealism, that is to say, built on the basis of a critique of the powers of reason. The precritical period of Kant's thought is interesting primarily, though not exclusively, for its anticipations of his later ideas. Kant was educated by Knutzen in the Wolff-Baumgarten version of Leibniz, and he was, like his master, an independent Leibnizian from the first, although it was many years before he made a decisive break with the Leibnizian way of thinking. The main influence operating against Leibniz in Kant's early thought was Newton, to whose work he had also been introduced by Knutzen. In the more narrowly philosophical field another independent Leibnizian, Christian August Crusius, proved an important subsidiary influence. Just when David Hume awakened Kant from his "dogmatic slumber" is uncertain, but it seems likely that Kant had moved some way in the direction of empiricism before that event took place.

**CAUSATION.** How little the early Kant had learned from Hume can be seen from some of his first metaphysical essays. In the *Principium Primorum Cognitionis Metaphysicae Nova Dilucidatio* (Königsberg, 1755) he discoursed in effect on the subject of causality, discussing at length the relationship of the Leibnizian principle of sufficient reason to the logical principles of identity and contradiction. Kant knew at this stage, as Crusius did, that Wolff's attempt to subordinate the real to the logical was a mistake, but he had only a hazy idea of what he was later to call the synthetic nature of propositions asserting real connections. He moved a step nearer his mature view in the 1763 essay on negative quantities (*Versuch, den Begriff der negativen Grössen in die Weltweisheit einzuführen*, Königsberg) when he pointed out that opposition in nature is quite different from opposition in logic: Two forces acting against one another are quite unlike a proposition in which the same predicate is simultaneously affirmed and denied. But in none of his writings of the time did Kant explicitly raise the question of the sphere of application of the causal principle, as Hume did.

**EXISTENCE.** Kant's failure to press home his questions on causation is paralleled in his otherwise striking treatment of existence in another work published in 1763, "The Only Possible Ground of Proof of God's Existence." He began this work by declaring that even if the proposition that existence is no predicate or determination of anything seems "strange and contradictory," it is nevertheless indubitable and certain. "It is not a fully correct expression to say: 'A sea unicorn is an existent animal'; we should put it the other way round and say: 'To a certain existing sea animal there belong the predicates that I think of as collectively constituting a sea unicorn.'" On these grounds Kant rejected the Cartesian version of the Ontological Argument. But he held, even so, that an alternative conceptual proof of God's existence could be found: Nothing could be conceived as possible unless (as the point had already been put in the *Nova Dilucidatio*) "whatever of reality there is in every possible notion do exist, and indeed, absolutely necessarily. ... Further, this complete reality must be united in a single being." There must, in other words, be a perfect being if there are to be any possibilities. Kant was to recall this proof in his derivation of the idea of the *ens realissimum* in the *Critique of Pure Reason*, but he then no longer believed that it had constitutive force. His treatment of attempts to produce causal proofs of God's existence in the *Critique* was also altogether more trenchant than in the precritical works, for though he saw there that the ordinary First Cause Argument was unsatisfactory, he regarded the Argument from Design as generally acceptable, even if not logically compulsive.

**METAPHYSICAL PROPOSITIONS.** Kant was more successful in another treatise written at the same period, "Untersuchungen über die Deutlichkeit der Grundsätze der natürlichen Theologie und der Moral" (On the Distinctness of the Principles of Natural Theology and Morals; 1764). The Berlin Academy had proposed the question, Are metaphysical truths generally, and the fundamental principles of natural theology and morals in particular, capable of proofs as distinct as those of geometry? If not, what is the true nature of their certainty? Kant answered by drawing a series of radical distinctions between argument in philosophy and argument in mathematics. The mathematician starts from definitions that are in effect arbitrary combinations of concepts; the philosopher must work toward definitions, not argue from them, since his business is to "analyze concepts which are given as confused." Mathematics contains few unanalyzable concepts and indemonstrable propositions; philosophy is full of them. Then too, the relationship

between mathematical ideas can always be observed *in concreto*, whereas the philosopher, having nothing to correspond to mathematical diagrams or symbolism, necessarily works on a more abstract level. The lesson of all this might seem to be that philosophical truths are incapable of strict demonstration, but Kant did not draw this conclusion in the case of natural theology, where he held to his attempted conceptual proof, though he inclined toward it in respect to “the primary grounds of morals.” In general, Kant’s tendency was to say that metaphysics must be an analytic activity that should follow a method that is fundamentally Newtonian: “It is far from the time for proceeding synthetically in metaphysics; only when analysis will have helped us to distinct concepts understood in their details will synthesis be able to subsume compounded cognitions under the simplest cognitions, as in mathematics” (*Critique of Practical Reason and Other Writings*, Beck translation, 1949, p. 275).

Kant viewed the prospects of attaining genuine metaphysical knowledge with increasing skepticism as the 1760s went on. In the enigmatic *Dreams of a Spirit-Seer* of 1766 he compared the thought constructions of metaphysics to the fantasies of Swedenborg, in a manner that is scarcely flattering to either. Metaphysical contentions are groundless, since metaphysical concepts such as spirit cannot be characterized in positive terms. To survive, metaphysics must change its nature and become a science of the limits of human knowledge. Kant’s skepticism about metaphysics was increased by his discovery of the antinomies, which is often dated 1769 although something like the third antinomy is to be found in the *Nova Dilucidatio*. Astonishingly, however, in his inaugural dissertation in 1770 he reverted in some degree to the old dogmatic conception of the subject and argued for the possibility of genuine knowledge of an intelligible world. But the main interest of the dissertation lies in its account of sensory knowledge, which prepared the way for the fundamental criticisms of metaphysical pretensions in the *Critique of Pure Reason*.

### THE INAUGURAL DISSERTATION

Kant’s Latin dissertation, “On the Form and Principles of the Sensible and Intelligible Worlds,” publicly defended on August 21, 1770, was his inaugural lecture as professor of logic and metaphysics at Königsberg. At least one of the themes of the dissertation, the status of the concept of space, represented a long-standing interest. As early as 1747 Kant had argued that the proposition that space has three dimensions is contingent; given a different law of the effects of different substances on one another, “an

extension with other properties and dimensions would have arisen. A science of all these possible kinds of space would undoubtedly be the highest enterprise which a finite understanding could undertake in the field of geometry” (“Living Forces,” Handyside translation, in *Kant’s Inaugural Dissertation and Early Writings on Space*, p. 12). Later, however, he regarded three-dimensionality as a necessary property of space, and used its necessity as a ground for rejecting Leibniz’ account of the concept. In a short essay on space published in 1768 Kant had seemed to suggest that Newton’s view of space as an absolute reality was the only alternative to Leibniz, but in the dissertation he rejected both theories and widened his treatment of the question so that it covered time as well as space. Despite this extension the dissertation is best viewed as directed mainly against Leibniz.

**SPACE AND TIME.** In general, Leibniz had followed the other great rationalists in interpreting perception as a confused form of thinking. Like Descartes, he had treated the deliverances of the senses as sometimes clear but never distinct. In the dissertation Kant developed two main arguments against this position. He maintained in the first place that it could not do justice to the special character of space and time, which are not, as Leibniz supposed, systems of relations abstracted from particular situations and confusedly apprehended, but rather unique individuals of which clear knowledge is presupposed in all perceptual description. The ideas of space and time are intuitive rather than conceptual in character; moreover, they are “pure” intuitions insofar as the essential nature of their referents is known in advance of experience and not as a result of it.

**SPACE AND GEOMETRY.** To reinforce this point Kant brought forward his second argument, that Leibniz’ theory could not account for the apodictic character of geometry. There was, Kant supposed, an essential relation between geometry and space, for geometry “contemplates the relations of space” and “does not demonstrate its universal propositions by apprehending the object through a universal concept, as is done in matters of reason, but by submitting it to the eyes as a singular intuition, as is done in matters of sense” (“Dissertation,” in *Kant’s Inaugural Discussion and Early Writings on Space*, Sec. 15 C). But if space is what Leibniz said it was and if, as Kant added, “all properties of space are borrowed only from external relations through experience,” then:

geometrical axioms do not possess universality, but only that comparative universality which is acquired through induction and holds only so

widely as it is observed; nor do they possess necessity, except such as depends on fixed laws of nature; nor have they any precision save such as is matter of arbitrary convention; and we might hope, as in empirical matters, some day to discover a space endowed with other primary affections, and perhaps even a rectilinear figure enclosed by two straight lines. (Sec. 15 D)

Kant's own account of space at this stage was that it "is not something objective and real, neither substance, nor accident, nor relation, but [something] subjective and ideal; it is, as it were, a schema, issuing by a constant law from the nature of the mind, for the co-ordinating of all outer *sensa* whatever" (Sec. 15D). One major advantage of this subjectivist view, in Kant's eyes, was that it explains the possibility of applying geometry to the physical world. Space being a universal form of sensibility, "nothing whatsoever ... can be given to the senses save in conformity with the primary axioms of space and the other consequences of its nature, as expounded by geometry" (Sec. 15 E).

**APPEARANCE AND REALITY.** Kant's view had another, more startling implication, namely that we cannot know things as they really are through sense perception. If space and time are contributed by the knowing mind, spatial and temporal objects will be altered in the very act of being apprehended. It follows that the world known through the senses—the world investigated by the physical sciences and familiar in everyday experience—can be no more than a phenomenal world. Kant was prepared to accept this conclusion in the dissertation, but he balanced it by saying that over and above this phenomenal world is another world of real objects, knowable not by the senses but by reason. Reason lacks intuitive powers—we cannot be acquainted with things as they are. But (and in this the contrast with the *Dreams* is at its strongest) reason possesses certain concepts of its own, among them "possibility, existence, necessity, substance, cause," by means of which it can arrive at a "symbolic cognition" of such things; that is, know some true propositions about them. The intellect, in its real as opposed to its logical use, can form the concept of a perfect being and use this both to measure the reality of other things and for moral purposes.

**ACHIEVEMENTS.** The doctrine of pure intellectual concepts in the dissertation is at best impressionistic and had to be completely rethought in the ten years that followed. But against this may be set Kant's positive achievements in the dissertation, seen from the point of view of his

future work. First, Kant had convinced himself that there is an absolute difference between sensing and thinking, and that sense experience need not be in any way confused. Second, he had worked out the main lines, though by no means all the details, of what was to be his mature theory of space and time. Third, he had revived the old antithesis of things real and things apparent, objects of the intellect and objects of the senses, to cope with the consequences of his views about space and time; in this way he was able to show (or so he thought) that physics gives us genuine knowledge, though only of appearances, and that the task of telling us about things as they really are is reserved for metaphysics. Fourth and last, he had recognized the existence of a special class of concepts, "given through the very nature of the intellect," and had seen that these have an important bearing on the question of the possibility of metaphysics.

What Kant had not done was to pose the problem of metaphysics with all its wider implications. As in the *Dreams*, he treated the question whether we have any knowledge of a world of pure spirit as one that is asked primarily for its theoretical interest. It was intellectual curiosity, that is to say, which at this stage prompted Kant to inquire whether physics and metaphysics could coexist, and, if they could, what should be said of their respective objects. He retained this curiosity when he wrote the *Critique of Pure Reason*, but it was not by then his only motive. For he had seen by 1781 that the question of the possibility of metaphysics was important not only to the academic philosopher, but because of its bearing on the universally interesting topics of God, freedom, and immortality, to the plain man as well; that it was a matter not just of intellectual, but also of moral, concern.

### CRITIQUE OF PURE REASON: THEME AND PRELIMINARIES

Kant's principal task in the *Critique of Pure Reason* was to determine the cognitive powers of reason, to find out what it could and could not achieve in the way of knowledge. The term *reason* in the title was intended in its generic sense, to cover the intellect as a whole; Kant was not exclusively interested in the reason that he himself distinguished from and opposed to understanding. He was, however, particularly concerned with the capacities of "pure" reason, that is, with what reason could know when operating by itself and not in association with another faculty. Kant believed it important to answer this question for two reasons. He saw that there are spheres (mathematics, for instance) in which it is plausible to claim that pure reason is a source of important truths. He

also saw that in another field, that of metaphysics, remarkable claims were advanced on reason's behalf: It was alleged that, by simply thinking, we could arrive at ultimate truth about the world, establishing thus a series of propositions whose certainty was unassailable and whose subject matter was of supreme importance. Kant, who had himself made this sort of claim in the dissertation, never doubted that what the metaphysician wants to say matters, but he did question his competence to say it. The fact that reason "precipitates itself into darkness and contradictions" once it enters this field struck him as deeply significant; the "intestine wars," the interminable disputes, of metaphysicians could only mean that their claims were pitched too high.

Nor was the scandal of metaphysics—the fact that nothing in metaphysics could be regarded as settled—of concern only to metaphysicians. By failing to make good his proofs, the metaphysician brought doubt on the acceptability of his conclusions, including such fundamental articles of belief as that God exists and that the will is free. In proposing a radical reexamination of the capacities of pure reason, Kant's ultimate motive was to safeguard such convictions by making clear that although they cannot be matters of knowledge, they can all the same be held to as matters of what he called pure rational faith.

**TYPES OF JUDGMENT.** In the preface to the *Critique*, Kant formulates his main question as "how much can understanding and reason know apart from all experience?" (A xvii). (The first edition is customarily referred to as A, the second edition as B.) In the introduction, he takes his first step toward an answer by substituting the formula "How are synthetic *a priori* judgments possible?" Two closely connected sets of distinctions lie behind these celebrated words. First, Kant distinguishes propositions that are *a priori* from all others; an *a priori* judgment "in being thought is thought as *necessary*" and is also thought "with strict universality, that is, in such a manner that no exception is allowed as possible" (B 3–4). *A priori* judgments have the twin characteristics of necessity and universality, neither of which can be found in conclusions from experience.

In holding that experience can present us with no more than contingent truths Kant echoes the views of many of his predecessors. But in his other distinction, between synthetic and analytic judgments, he shows greater originality. A judgment is analytic, he explains, if what is thought in the predicate-concept has already been thought in the subject-concept; a judgment is synthetic if

this condition does not obtain. Thus, "All bodies are extended" is analytic because our idea of a body is of something that is extended or occupies space; "All bodies have weight" is synthetic because the notion of weight is not comprised in the notion of body (we learn by experience that bodies have weight). In analytic judgments, again, the connection of subject and predicate is "thought through identity"; or, as Kant puts it elsewhere in the *Critique*, the highest principle of all analytic judgments is the principle of contradiction. It follows from this that every analytic judgment is *a priori* in that it is true or false without regard to experience; every analytic judgment is either necessarily true or necessarily false, and we establish its truth or falsity by reference only to definitions of the terms it contains and to the principle of contradiction. Synthetic judgments, by contrast, require for their authentication a different sort of reference, since in their case the connection of subject and predicate terms is "thought without identity." In the case of everyday judgments of fact, for example, we need to consult experience to see whether the connection asserted actually holds.

So far Kant's distinction is simply a more elaborate version of Hume's division of propositions into those that assert relations of ideas and those that express matters of fact and existence, a version inferior to Hume's in that it is formally tied to statements of the subject-predicate form. But at this point Kant gives the distinction a fresh twist by asserting that there are judgments that are both synthetic and *a priori*, thus cutting across the usual classifications. Nearly all the propositions of mathematics answer this description, according to Kant; he also thinks it obvious that "*natural science (physics) contains a priori synthetic judgments as principles.*" He gives two examples: "in all changes of the material world the quantity of matter remains unchanged; and ... in all communication of motion action and reaction must always be equal" (B 17). The very existence of these judgments shows that reason has special cognitive powers of its own, and so lends plausibility to the claims of metaphysicians. But before accepting the claims of metaphysicians, Kant suggests, we need to ask ourselves how (under what conditions) it is possible to assert judgments of this type in the two fields concerned. Only when this question is answered can we decide whether metaphysicians can draw support from the example of mathematics and "pure" physics. This inquiry is what Kant is concerned with in the first half of the *Critique*.

**ANALYTIC AND SYNTHETIC.** The terms in which Kant states his problem seem at first sight clear, but the clarity diminishes on closer inspection. There is the criticism

that he offers a dual account of the analytic-synthetic distinction, once in psychological and once in logical terms, and the criticism that reference to the principle of contradiction alone is inadequate for the logical formulation of the distinction (he should have referred to logical laws generally). Apart from these two matters, Kant's treatment is marred by a failure to offer any discussion of his key idea, "what is thought in a concept." This omission is the more remarkable because Kant in fact had views on the subject of definition, views that are hard to reconcile with his apparent assumption that every judgment is unequivocally analytic or synthetic. Elsewhere in the *Critique* he states that, according to the real meaning of "definition," an empirical concept "cannot be defined at all, but only made explicit" (B 755). He means that we cannot give the "real essence" (in Locke's terminology) of such a concept, but only its "nominal essence," or conventional signification, which is liable to change as knowledge increases or interests shift. If this is correct, it seems to be only by convention, or provisionally, that the judgment "All bodies are extended" is analytic and the judgment "All bodies have weight" synthetic.

Nor is Kant's other distinction, between a priori and a posteriori, as simple as he pretends. He tries to clarify it by explaining that the first class of judgments have the characteristics of necessity and universality, which serve as criteria that are "inseparable from one another." He fails to notice, however, that the necessity that belongs to synthetic a priori judgments must on his own account differ from that which characterizes analytic judgments. Analytic judgments are, or rather claim to be, logically necessary—to deny a true analytic judgment would be, if Kant is correct, to dispute the validity of the law of contradiction. But though no synthetic judgment can contravene the laws of logic, none can be true in virtue of these laws and of meanings alone. Accordingly, if any synthetic judgment is to be described as necessary, it must be necessary in some further sense.

Kant recognizes in practice that the synthetic a priori judgments he takes to be valid have their own special kind of necessity. In his own terminology, they are "transcendentally" necessary; necessary, that is to say, if we are to have the knowledge and experience we actually have. But he would have done better to acknowledge the ambiguity in his term *a priori* from the outset. It would also have been helpful had he given some elucidation of his statement that, when a judgment is thought with strict universality, "no exception is allowed as possible." He cannot mean that no exception is logically possible, or every a priori judgment would be analytic. But he does not, at

least at this early stage, make clear what other sort of possibility he has in mind.

## TRANSCENDENTAL AESTHETIC

Kant's next step in the solution of the problem of how synthetic a priori judgments are possible is to examine the two types of case in which, in his view, we undoubtedly can make synthetic a priori judgments, and then to exhibit the bearing of his results on the possibility of metaphysical knowledge. In his short but important *Prolegomena to Every Future Metaphysics* he approaches these tasks directly. In the *Critique* itself his method is more roundabout, since he proposes there to delineate the entire cognitive powers of the mind and so to clarify the background against which synthetic a priori judgments are made. This leads him to undertake an inquiry first into the a priori elements involved in sensory knowledge (the "Transcendental Aesthetic") and then into the corresponding elements involved in thought (the "Transcendental Logic"). The sharp distinction between the senses and the intellect argued for in the dissertation is the obvious basis of this division.

**A PRIORI INTUITIONS.** It seems at first sight contradictory to say that there might be a priori elements involved in sensory knowledge. According to an old philosophical and psychological tradition, sensation is an essentially passive affair; the senses present us with data and we have no choice but to accept. Kant was quite ready to agree to this as a general account of sensation. But he was persuaded that there are some features of sensory experience that cannot be accepted as empirically given.

Kant identifies these features by a process similar to that in the dissertation: an examination of our ideas of space and time. These ideas, he argues, represent the form of experience rather than its matter; through them we structure the sensory given in the very act of sensing it. To establish this position Kant appeals to a variety of considerations.

First, he insists on the fundamental and ubiquitous character of space and time, as opposed to features like color and sound. Spatial predicates apply to whatever we know through the five senses, temporal predicates both to these and to the immediately experienced flow of our inner lives. Second, he argues that we cannot acquire the ideas of space and time by reflecting on what is empirically given. Some philosophers had said that we come by the idea of space by noticing such things as that one object is adjacent to another, and that we come by the idea of time by observing the way in which events suc-

ceed, are simultaneous with, or precede one another. Kant points out that the very description of such situations presupposes familiarity with space and time as such. For to know what is meant by saying that one thing is “next to” or “on top of” another we need to appreciate how the things in question are situated in a wider spatial framework, which in turn falls within a yet wider spatial system, until we come to the thought of space as a whole. Particular spaces are not instances of space, but limitations of it, and space is accordingly a special sort of particular. The same argument applies to time. Adding to these two points the fact that we know certain things to be necessarily true of space and time (space has only three dimensions, different times are not simultaneous but successive), Kant infers that the ideas of space and time are not only “intuitions,” but “*a priori* intuitions.”

**MATHEMATICS.** Kant finds confirmation for his view of space and time exactly as he had in the dissertation: in the thought that this view alone can explain the possibility of pure and applied mathematics. Pure geometry is possible because we are able to “construct,” or show the real possibility of, its concepts in pure intuition. An experiment conducted in imagination shows at once that a triangle is a real spatial possibility, whereas a figure bounded by two straight lines is not. Applied geometry is possible because whatever is apprehended by the senses must necessarily accord with the forms of sensibility. Kant attempts at various points in his writings to extend his doctrine of the importance of pure intuition for mathematical thinking from geometry to the other parts of mathematics, but it cannot be said that he is ever convincing on this point. His reasons for saying that “seven and five are twelve” is a synthetic proposition were sharply and properly criticized by Gottlob Frege. His account of algebra (B 745, 762) is so sketchy as to be virtually unintelligible. Kant tries to say that in algebra there is a “symbolic construction” corresponding to the “ostensive construction” of the concepts of geometry, but it is not in the least clear what this has to do with the pure intuition of either space or time.

Some critics speak as if Kant’s failure to produce a satisfactory philosophy of mathematics invalidated the whole “Aesthetic,” and it is true that the central point of this part of his work is destroyed if his main contentions about mathematics are rejected. Kant’s explanations fall to the ground if it turns out that there is no intrinsic connection between mathematics and space and time, or if it is held that mathematical propositions are analytic, not synthetic *a priori*. But it does not immediately follow that the whole Kantian doctrine of space and time must be

rejected, for many of his arguments on this matter are independent of his philosophy of mathematics. Nor is it decisive against him that the treatment of space and time in modern physics is very different from his; he claims to be dealing with the space and time of immediate perception.

**SIGNIFICANCE.** Apart from the questions about truth, however, it is vital to appreciate the importance of the conclusions of the “Aesthetic” in the economy of the *Critique of Pure Reason* as a whole. The “transcendental ideality” of space and time carries with it, for Kant, the proposition that whatever we know through the senses (including “inner sense”) is phenomenal; Kant’s celebrated distinction between appearances and things-in-themselves has its origin, if not its justification, at this point. And the view that space and time are *a priori* forms of intuition is not only the model on which Kant constructed his theory of categories as concepts embodying the pure thought of an object in general; the view is carried over intact into the “Transcendental Analytic,” and plays a crucial part there. To treat the theories of the “Aesthetic” as if they merely embodied a series of views that Kant had outgrown by the time he completed the *Critique*, as some commentators have proposed to do, is not in accord with Kant’s own intentions. It is also to ignore a series of arguments that are of independent philosophical interest, and that demand careful notice from anyone writing on the philosophy of perception.

#### PURE CONCEPTS OF THE UNDERSTANDING

The main contentions of the aesthetic are to be found in the dissertation. Of the doctrine of pure intellectual concepts put forward in that inaugural lecture, on the other hand, almost nothing survives in the *Critique of Pure Reason*.

**OBJECTIVE REFERENCE.** In the dissertation Kant argues along two lines: First, that pure intellectual concepts are not derived from sense experience (they could not be described as “pure” if they were); and second, that they serve to give us information about things as they really are. Soon after writing this work, however, Kant realized that there was a fundamental difficulty in this position, a difficulty he stated at length in a letter to his friend Marcus Herz dated February 21, 1772. It was that of knowing how “pure” concepts could be said to determine an object of any kind. To elucidate the difficulty, Kant isolated two contrasting types of intelligence, *intellectus ectypus*, “which derives the data of its logical procedure from the

sensuous intuition of things,” and *intellectus archetypus*, “on whose intuition the things themselves are grounded.” The concepts of the first type of intelligence, deriving as they do from objects, have a guaranteed relationship to objects. The concepts of the second type determine objects, because, in this sort of case, thinking itself brings objects into existence in the same way in which “the ideas in the Divine Mind are the archetypes of things.” But the human intelligence, as described in the dissertation, answers to neither description, for some of its concepts are not empirically derived and yet none of its thinking is creative in the sense specified. The problem then arises, How can these concepts be said to have objective reference; how can we know that in using them we are thinking about anything actual? It is this problem that Kant professes to have solved in the *Critique of Pure Reason*. Roughly speaking, his solution is that pure concepts can be shown to determine an object if the object is phenomenal. By contrast, when an attempt is made to use them to specify characteristics of “things in general,” there is no guarantee that anything significant is being said.

**ANALYTIC AND DIALECTIC.** The details of Kant’s explanation of how pure concepts can be said to have objective reference is to be found in the lengthy section of the *Critique* labeled “Transcendental Logic” and divided into two main parts, “Transcendental Analytic” and “Transcendental Dialectic.”

The first part contains an inventory of what at this point Kant calls pure concepts of the understanding, or categories, with an account of the function they perform in human knowledge and a series of arguments purporting to show that, in the absence of such pure concepts, objective knowledge would be impossible for human beings. In addition, the “Analytic” lists the principles that rest on these pure concepts and offers independent proofs of these principles. Transcendental analytic is said by Kant to be a “logic of truth,” insofar as “no knowledge can contradict it without at once losing all content, that is, all relation to an object, and therefore all truth” (B 87). It deals, in short, with the proper use of a priori concepts, which is the use they have when they provide a framework for empirical inquiries.

Transcendental dialectic is introduced as if it were merely the negative counterpart of analytic—as if its sole purpose were to expose the illusions generated when dogmatic philosophers, unaware of the sensuous conditions under which alone we can make successful use of a priori concepts, attempt to apply them outside the sphere of possible experience. In fact a large part of the section

titled “Dialectic” is devoted to the exposure of metaphysical sophistries. But insofar as Kant recognizes in this part of his work the existence of a further set of intellectual operations involved in scientific inquiry, he seeks to show that the faculty of theoretical reason as well as that of the understanding has its appropriate pure employment.

**JUDGMENT OR BELIEF.** A good way to approach the central doctrines of the analytic is to see them as an intended answer to Hume. Kant’s knowledge of Hume was limited—he had no firsthand acquaintance with the *Treatise of Human Nature*—but he grasped the importance of many of Hume’s most challenging points. For instance, Hume had argued that “*belief is more properly an act of the sensitive, than of the cogitative part of our natures*” (*Treatise*, edited by L. A. Selby-Bigge, 1888, Book I, Part IV, Sec. 1, p. 183); in the last resort it is a matter of subjective conviction. It is one of Kant’s main objects in the analytic to demonstrate that such a view cannot do justice to an all-important feature of what Hume calls belief and he calls judgment, namely, its claim to be true. When I judge that something is the case I do not merely commit myself to a certain assertion; there is a sense in which I commit all rational persons too, for I purport to state what holds objectively, that is to say for everyone. To make judgment primarily a matter of feeling, something private to an individual person, is to leave out what is most characteristic of it. Similarly, to explain thinking about matters of fact and existence in terms of the association of ideas, as Hume did, is to confuse the objective with the subjective, to put science on the level of idle reverie. Empirical thinking, to deserve its name, must proceed according to rules, and there is all the difference in the world between a rule, which cannot of its nature be private, and association, which is the connecting of ideas on a purely personal plane.

**THE UNITY OF EXPERIENCE.** There are many philosophers who would accept this criticism of Hume but would deny that empirical thinking involves not only rules, but rules that are a priori or necessary rules. To understand why Kant asserts that thinking must proceed according to necessary rules, we must explain his attitude to another of Hume’s doctrines, the famous contention that “all our experimental conclusions proceed upon the supposition that the future will be conformable to the past” (*Enquiry concerning Human Understanding*, Sec. IV, Part II). Kant agrees with Hume that empirical knowledge involves connecting one part or element of experience with another; he agrees too that connection of this sort (“synthesis”) proceeds on a principle that is neither

analytically true nor empirically probable. But he refuses to follow Hume in deriving the principle from “Custom or Habit,” for he sees more clearly than Hume the consequences of adopting this “sceptical solution.” If it were really the case that events were as “loose and separate” as Hume supposed, not only should we be deprived of any insight into the connections of things, but we should have no unitary consciousness of any sort. For it is a necessary condition of having a unitary consciousness that we be able to relate what is happening here and now to things and events that lie outside our immediate purview; if the ability to relate is not a real possibility, then neither is unitary consciousness. What Kant calls in one place (A 113) “the thoroughgoing affinity of appearances” (the fact that appearances are capable of being connected in a single experience) thus relates closely to the ability of the observer to recognize himself as a single person with diverse experiences. In fact the relation is one of mutual implication.

It may be useful to cite Kant’s explanation as he gave it in the first edition of the *Critique*, in a passage in which all the most characteristic ideas of the “Analytic” appear and which also illustrates Kant’s persistent but nonetheless questionable tendency to move from saying that unity of consciousness means that appearances must be capable of connection to the conclusion that they must be capable of connection according to universal and necessary laws.

There can be in us no items of knowledge, no connection or unity of one item of knowledge with another, without that unity of consciousness which precedes all data of intuitions, and by relation to which representation of objects is alone possible. This pure original unchangeable consciousness I shall name *transcendental apperception*. ... This transcendental unity of apperception forms out of all possible appearances, which can stand alongside one another in one experience, a connection of all these representations according to laws. For this unity of consciousness would be impossible if the mind in knowledge of the manifold could not become conscious of the identity of function whereby it synthetically combines it in one knowledge. The original and necessary consciousness of the identity of the self is thus at the same time a consciousness of an equally necessary unity of the synthesis of all appearances according to concepts, that is, according to rules, which not only make them necessarily reproducible but also in

so doing determine an object for their intuition, that is, the concept of something wherein they are necessarily interconnected. (A 107–108)

**ROLE OF CATEGORIES.** If the synthesis of appearances is to proceed in accordance with necessary laws, we must clearly operate not just with empirical but also with a priori concepts. But this must not be taken to mean that some items or features of fact can be known apart from all experience. For the role of an a priori concept is fundamentally different from that of its empirical counterpart. Categories are concepts of a higher order than empirical concepts; like the ideas of space and time, they have to do with the form of experience rather than its matter. Our possession of categories accordingly supplies no knowledge of particular things; categories are fertile only when brought to bear on empirical data. Thus, because we hold to the a priori concept of cause, we interrogate nature in a certain way; thanks to it, we refuse to believe that there could be an uncaused event. But the answers we get to our interrogation depend primarily not on the form of our questions, but on what turns up in experience. Those who accuse Kant of having believed in the material a priori have failed to understand his theory.

To summarize this part of Kant’s argument: If we are to have knowledge (and it is Kant’s assumption that we do), various conditions must be fulfilled. The different items that fall within our experience must be capable of being connected in a single consciousness; there can be no happenings that are genuinely loose and separate. But the connections thus demanded must be objective connections—they must hold not just for my consciousness, but for “consciousness in general,” for everyone’s. An objective connection for Kant is a connection determined by a rule, and a rule is of its nature something that claims intersubjective validity. Finally, if we are to establish the operation of empirical rules we must proceed in accordance with nonempirical rules of a higher order, rules that ensure that our different experiences are capable of connection within a single experience.

**JUDGMENTS.** In view of the close relation Kant sees between the making of judgments and the use of a priori concepts, it is perhaps not surprising that he tries to arrive at a full list of such concepts by scrutinizing the formal properties of judgments. In this connection he invokes the doctrines of general or formal logic, a science he believed had been brought to completion at a single stroke by Aristotle. Few scholars have been convinced by this section of his argument, for it seems clear that Kant adapted the list of judgment forms to suit his list of cate-

gories, rather than deriving the categories from the judgment forms. In any case, it is not obvious how formal logic, which is a logic of consistency, can supply a clue to the content of what professes to be a logic of truth.

**IMAGINATION AND UNDERSTANDING.** In the first part of the “Analytic” Kant has much to say not only about concepts, judgments, and the understanding but also about the imagination. For example, he remarks in a cryptic passage:

Synthesis in general is the mere result of the power of imagination, a blind but indispensable function in the soul, without which we should have no knowledge whatsoever, but of which we are scarcely ever conscious. To bring this synthesis to concepts is a function which belongs to understanding, and it is through this function of the understanding that we first obtain knowledge properly so called. (B 103)

The contrasting and, in places, overlapping roles of understanding and imagination are among the most puzzling features of Kant’s exposition. The reason why they are both introduced is related to the fact that, in the second edition of the *Critique of Pure Reason* in particular, Kant was concerned with two quite distinct questions. He first asked himself what conditions have to be fulfilled if any sort of discursive consciousness is to have objective knowledge; he then went on to put the question as it relates to the human discursive consciousness, which not only intuits data passively, but does so under the particular forms of space and time. When the first question is uppermost Kant tends to speak of the understanding; when the second is to the fore, he brings in the imagination as well. The passage quoted above, typical of many, suggests that it is the business of the imagination to connect, whereas that of the understanding is to make explicit the principles on which the connecting proceeds. But in one chapter, “Schematism of the Pure Concepts of Understanding,” a more satisfying account of the relationship is offered.

**SCHEMATA.** The problem of the chapter on what Kant called “schematism” is the central problem of the analytic: How can concepts that do not originate in experience find application in experience? At first Kant speaks as if there were no comparable difficulty in the case of concepts originating in experience, although he later makes clear that there are schemata corresponding both to empirical and to mathematical concepts. To possess the concept triangle is to know its formal definition, to be

able to frame intelligible sentences containing the word *triangle*, and so on; to possess the schema corresponding to the concept triangle is to be able to envisage the variety of things to which the word *triangle* applies. Thus for Kant a schema is not an image, but a capacity to form images or (perhaps) to construct models. Pure concepts of the understanding are such that they “can never be brought into any image whatsoever” (B 181); the thought they embody, springing from the pure intellect, cannot be pictured or imagined. Yet there must be some connection between the abstract idea and the experienced world to which that idea is expected to apply; it must be possible to specify the empirical circumstances in which pure concepts of the understanding can find application. Kant thinks that for the categories this requirement is met by the fact that we can find for each of them a “transcendental schema,” which is, he explains, a “transcendental determination of time.” Without such a schema the categories would be devoid of “sense and significance,” except in a logical (verbal) way. With it, use of the categories is clearly restricted to the range of things that fall within time—meaning, for Kant, restricted to phenomena.

The meaning of this baffling doctrine can perhaps best be grasped through Kant’s examples of schemata:

The schema of substance is permanence of the real in time, that is, the representation of the real as a substrate of empirical determination of time in general. ... The schema of cause... is the real upon which, whenever posited, something else always follows. It consists, therefore, in the succession of the manifold, in so far as that succession is subject to a rule. ... The schema of necessity is existence of an object at all times. (B 183–184)

It emerges from these cryptic sentences that the transcendental schema is something like an empirical counterpart of the pure category. It is what the latter means when translated into phenomenal terms. In Kant’s own words, the schema is “properly, only the phenomenon, or sensible concept, of an object in agreement with the category” (B 186). A category without its corresponding “sensible concept” would be a bare abstraction, virtually without significance. Insofar as he argues that schematization is the work of the imagination, Kant has found a genuine function for the imagination to perform.

**ANALYTIC OF PRINCIPLES: PURE PHYSICS.** In the first half of the “Analytic” Kant undertook to produce a “transcendental deduction,” that is, a general proof of validity, of the categories. In the second half of the “Analytic” he

gives a series of demonstrations of the synthetic a priori principles that rest on individual categories.

The categories are divided, for this and other purposes, into four groups: quantity, quality, relation, and modality. The four sets of corresponding principles are labeled axioms of intuition, anticipations of perception, analogies of experience, and postulates of empirical thought in general. Only one principle falls under each of the first two classes; the third contains a general principle and three more specific principles; the fourth contains three separate though closely connected principles. The first two classes are grouped together as “mathematical” principles; the third and fourth are described as “dynamical.” Mathematical principles are said to be “immediately evident” and again to be “constitutive of their objects”; they apply directly to appearances. Dynamical principles are concerned with “the existence of such appearances and their relation to one another in respect of their existence.” They are no less necessary than mathematical principles, but must be distinguished from them “in the nature of their evidence” and in that they are not “constitutive” but “regulative.”

Behind this formidable façade some interesting ideas are hidden. In the first place, Kant makes stimulating though not altogether convincing remarks on the subject of proving principles of the understanding. The statement that every event has a cause carries strict necessity with it and therefore cannot be grounded on an inductive survey of empirical evidence. But equally it is not analytic, and so not open to straightforward conceptual proof. To be assured of its authenticity we consequently require a different type of argument altogether, which Kant calls a “transcendental” argument “from the possibility of experience.” His idea is that only if the principles of the understanding are taken to be operative and in order can we have the type of experience we in fact have. Kant perhaps supposes that this type of proof is logically compulsive, but if so he overlooks the difficulty of setting up the original premise, of being sure that only if such-and-such were true should we have the experiences we have. But even with this defect his procedure has an immediate appeal, and is not without modern imitators.

**AXIOMS OF INTUITION.** The details of the particular arguments for the principles corresponding to the categories also deserve careful attention. The principle of axioms of intuition, that “all intuitions are extended magnitudes,” is perhaps the most difficult to take seriously, since what it purports to prove has apparently already been dealt with in the “Aesthetic.” Kant is once more ask-

ing questions about the application of mathematics to the world; in this section of the *Critique* the problem that apparently troubles him is how we know that inquiries about sizes or areas are always appropriate when we are dealing with things that occupy space. His solution is that they must be appropriate, since every such thing can be regarded as an aggregate of parts produced by the observer as he synthesizes his experiences. “I cannot represent to myself a line, however short, without drawing it in thought, that is, generating from a point all its parts one after another” (B 203).

**ANTICIPATIONS OF PERCEPTION.** Under the term “anticipations of perception” Kant is concerned with the question of the applicability of mathematics to sensations. What guarantee have we, he asks, that every sensation will turn out to have a determinate degree, in principle quantifiable? Might we not find, for instance, that an object is colored but with no precise depth of saturation, or a smell present in a room but with no specific magnitude? Kant attempts to rule out such possibilities by attention to the formal properties of sensations. We cannot anticipate the matter of sensation, but we can say in advance of experience that every sensation will have intensive magnitude, that is, a determinate degree, because it is possible to think of any given sensation as fading away until it is imperceptible, and conversely as being built up by continuous transitions on a scale from zero to the magnitude it has. Whatever may be the merits of this solution, there can be no doubt of the importance, and for that matter the novelty, of the question Kant asks here.

**ANALOGIES OF EXPERIENCE.** The section on the analogies of experience contains ideas as significant as any in Kant’s writings.

*The permanence of substance.* The principle of the first analogy is that of the permanence of substance: “in all change of appearances substance is permanent; its quantum in nature is neither increased nor diminished.” To believe in the permanence of substance is to believe that, whatever happens, nothing goes completely out of existence and nothing totally new is created: All change is transformation. Kant justifies the acceptance of this presupposition (which in his view, it should be remembered, applies only to things phenomenal) by arguing that without it we could not have a unitary temporal system. Coexistence and succession make sense only against a background that abides, and since time itself cannot be perceived, that background has got to be one of permanent things. This does not mean that we can determine a

priori what form the permanent will take; empirical scientists are to pronounce on that question, and their answers may obviously change from time to time. All that Kant seeks to rule out is the possibility that there might be no permanent at all. His argument is defective at a vital point here, but presumably he is saying that if things could go completely out of existence, so that it would make no sense to ask what became of them, the establishment of connections between one part of experience and another would be impossible. Experience would be (or at least might be) full of unbridgeable gaps, with the result that no one set of happenings could be integrated with another, and the unity of time would be totally destroyed.

**Causation.** Kant carries his argument further in his discussion of the second and third analogies, in which he argues for the necessary operation of the concepts of cause and reciprocity (causal interaction). But just as the notion of substance he justifies is very different from that held by metaphysicians, so is the Kantian concept of cause different from that of, say, Leibniz; it seems at first sight much closer to Hume's idea of a cause as an invariable antecedent. Causality for Kant as for Hume is a relation between successive events; a cause is an event that regularly precedes its effect. But whereas Hume is content to treat the occurrence of regular sequences as an ultimate and entirely contingent fact, Kant believes that without the presumption of sequences that are regular (determined by a rule) there could be no knowledge of objective succession. His reason is that we have to distinguish successions that happen only in ourselves, successions merely in our apprehension, from those that occur in the objective world and are independent of us. We can do this only if an objective sequence is defined as a sequence happening according to a rule. The objective world is a world of events the occurrence of each of which determines the precise place in time of some other event. But though events are necessarily connected in this way, we must not conclude that causal connections can be established a priori; for Kant as for Hume causal propositions are one and all synthetic and empirical. All we can know a priori is that there are such connections to be found, provided we have the skill or good fortune to discover them.

**POSTULATES OF EMPIRICAL THOUGHT.** One way of expressing Kant's attitude to substance and causality is to say that he thinks the principle of substance licenses us to ask the question, What became of that? Whenever something happens, and that the principle of causality licenses the parallel question, What brought that about? If someone tried to say that things might go out of existence alto-

gether, or happen for no reason at all, Kant would say that these were logical but not real possibilities. The contrast between real and logical possibility is explored by Kant in the section "The Postulates of Empirical Thought." This section contains an explanation of the notions of possibility, actuality, and necessity from the critical point of view. By "really possible" Kant means "that which agrees with the formal conditions of experience, that is, with the conditions of intuition and of concepts" (B 265). A two-sided figure enclosing a space is not really possible, though its concept is not self-contradictory, because such a figure does not accord with the formal conditions of intuition. Telepathy and precognition are not real possibilities; they "cannot be based on experience and its known laws" (B 270), presumably because their actuality would violate some principle of the understanding, although Kant fails to make the point clear. The notion of real possibility is for Kant intermediate between logical and empirical possibility. We need it and can use it only because the world we have to deal with is a world that is not independently existent, but has its being in essential relation to consciousness.

**PHENOMENA AND THINGS-IN-THEMSELVES.** The distinction between phenomena and things-in-themselves, insisted on in the "Aesthetic" to explain our having a priori knowledge of the properties of space and time, is invoked again in the "Analytic" to account for "pure physics." If the world we confronted were one of things-in-themselves, a priori knowledge of it, even of the very restricted sort for which Kant argues, would be quite impossible. The fact that we have such knowledge—that we possess the principles discussed above—is taken by Kant as proof that the objects of our knowledge are phenomena or appearances. He does not mean by this, however, that they are private objects, at least insofar as they are spatial. The world we know in everyday and scientific experience is common to many observers; if not independent of consciousness as such, it is independent of particular consciousnesses. Parts of it are known only to particular experiencers—my inner life, for example, is accessible only to me—but that does not affect the general point.

Kant's acceptance of the distinction between phenomena and things-in-themselves has met with much criticism. Without the idea of the thing-in-itself, said his contemporary F. H. Jacobi, we cannot enter the world of the *Critique of Pure Reason*; with it we cannot remain inside. At the end of the "Analytic" Kant tries to defend himself against criticism of this sort by arguing that though he says that the objects of experience are phe-

nomena and is prepared to admit that the obverse of a phenomenon is a noumenon or intelligible object, he is committed to noumena only in a negative sense. Having said that the categories, one of which is existence, apply only to phenomena, he cannot with consistency hold any other view. Nor is his position at this stage as devoid of logic as some have tried to make out. After all, to describe things as phenomena he does not need to assert that there actually are things of a different kind; he needs only the idea of such things. To talk about things as they might be in themselves is no more objectionable than to speak of an *intellectus archetypus*, as Kant did in the letter to Herz, or of an intuitive understanding, as he constantly does in both the *Critique of Pure Reason* and the *Critique of Judgment*.

### THE ELIMINATION OF DOGMATIC METAPHYSICS

At the end of the section of the *Critique of Pure Reason* devoted to the transcendental analytic, there is a passage that can be taken as summarizing the second stage in Kant's emancipation from Leibnizian rationalism:

The Transcendental Analytic leads to this important conclusion, that the most the understanding can achieve *a priori* is to anticipate the form of a possible experience in general. And since that which is not appearance cannot be an object of experience, the understanding can never transcend those limits of sensibility within which alone objects can be given to us. Its principles are merely rules for the exposition of appearances; and the proud name of an Ontology that presumptuously claims to supply, in systematic doctrinal form, synthetic *a priori* knowledge of things in general ... must, therefore, give place to the modest title of a mere Analytic of pure understanding. (B 303)

Kant thus repudiates the possibility of knowledge through pure concepts of things as they really are; in 1770 he had still clung to it. Having disposed of ontology, Kant needed to consider, to complete the negative side of his work, the tenability of the remaining parts of metaphysics (rational psychology, rational cosmology, and natural theology in Baumgarten's classification), and this he did in the section titled "Transcendental Dialectic." To complete his own alternative to rationalism he needed to clarify the status of the propositions involved in "pure practical faith." His attempt to meet this requirement is made at the very end of the *Critique*, especially in the chapter "The Canon of Pure Reason" (B 823ff.).

REASON. Most of the conclusions of the "Dialectic" follow directly from those of the "Analytic," though there are new points of interest. As in the "Analytic," Kant's views are expressed inside a framework that is heavily scholastic. Kant claimed that human beings have an intellectual faculty in addition to the understanding. This additional faculty is reason, and it is equipped with a set of *a priori* concepts of its own, technically known as ideas of reason. An idea of reason can have no object corresponding to it in sense experience, for the ambition of reason is to arrive at absolute totality in the series of conditions for the empirically given, and in this way to grasp the unconditioned that falls outside experience altogether. However, this ambition can never be realized, and the only proper function for reason in its theoretical capacity is to regulate the operations of the understanding by encouraging it to pursue the search for conditions to the maximum extent that is empirically possible.

THE KNOWING SUBJECT. Kant's handling of the "psychological idea" at the beginning of the main part of the "Dialectic" is exceptionally brilliant. He maintains in the "Analytic" that what he there calls the "I think," or the unity of apperception, is the ultimate condition of experience, in the sense of being the logical subject of experience or the point to which all experience relates. All experience is experience for a subject; whatever thoughts or feelings I have I must be capable of recognizing as my thoughts or feelings. But the subject here referred to is not something substantial; it is merely a logical requirement, in that nothing follows about the nature of my soul or self from the fact that I say "I think." So far from being "an abiding and continuing intuition" (the sort of thing Hume vainly sought in the flow of his inner consciousness), for Kant the "representation 'I' ... [is] simple, and in itself completely empty ... we cannot even say that this is a concept, but only that it is a bare consciousness which accompanies all concepts. Through this I or he or it (the thing) which thinks, nothing further is represented than a transcendental subject of thoughts = X" (B 404). The same view is expressed in an earlier passage in the *Critique*, where Kant says that "in the synthetic original unity of apperception, I am conscious of, myself, not as I appear to myself, nor as I am in myself, but [I am conscious] only that I am. This representation is a *thought*, not an *intuition*" (B 157).

REFUTATION OF RATIONAL PSYCHOLOGY. These subtleties are unknown to the exponents of rational psychology, who develop the whole of their teaching around a "single text," which is "I think." From the fact that I am

the subject of all my thoughts they infer that I am a thinking substance; from the fact that the “I” of apperception is logically simple they conclude that I am, in substance, simple and not composite. The proposition that “in all the manifold of which I am conscious I am identical with myself” is taken by them as implying that I am possessed of continuing personal identity. Finally, my distinguishing my own existence as a thinking being from that of other things, including my own body, is put forward as proof that I am really distinct from such things and so could in principle exist in complete independence of them. None of these inferences is justified, for in each case a move is attempted from an analytically true premise to a synthetic conclusion. As Kant remarks, “it would, indeed, be surprising if what in other cases requires so much labour to determine—namely, what, of all that is presented in intuition, is substance, and further, whether this substance can be simple ...—should be thus given me directly, as if by revelation, in the poorest of all representations” (B 408).

**MIND AND BODY.** Kant presents the doctrines of rational psychology in his own idiosyncratic way, but anyone who reflects on the theories of Descartes will see that Kant was by no means attacking men of straw. Kant’s treatment of the fourth paralogism, “of Ideality,” is of special interest in this connection. Descartes inferred from his *cogito* argument that mind and body were separate in substance, which meant that the first could exist apart from the second. Bound up with this was the view that I am immediately aware of myself as a mind, but need to infer the existence of material things, which is in principle open to doubt. A great many philosophers have subscribed to this opinion, but Kant thought he could show it to be definitively false. In order to say that my inner experiences come one before another I need to observe them against a permanent background, and this can only be a background of external objects, for there is nothing permanent in the flow of inner experience. As Kant put it in the second edition, in which he transposed the argument to the discussion of existence in connection with the postulates of empirical thought), “*The mere, but empirically determined, consciousness of my own existence proves the existence of objects in space outside me*” (B 275). Kant is in no sense a behaviorist; he thinks that empirical self-knowledge is to be achieved through inner sense and declares in one passage that, for empirical purposes, dualism of soul and body must be taken as correct. Yet his commitment to “empirical realism” is quite unambiguous.

**THE ANTI-NOMIES.** Of the remaining parts of the “Dialectic,” only the sections on the antinomies and on the existence of God can be discussed here. In the “Antinomy of Pure Reason,” Kant first sets out a series of pairs of metaphysical doctrines (which he says have to do with cosmology but which are in fact of wider interest). The two doctrines in each pair seem to contradict one another directly. He then produces for each pair what he regards as watertight proofs of both sides of the case, maintaining that if we adopt the dogmatic standpoint assumed without question by the parties to the dispute, we can prove, for example, both that the world has a beginning in time and that it has no beginning in time, both that “causality in accordance with laws of nature is not the only causality” and that “everything in the world takes place solely in accordance with laws of nature.” Thus Kant exhibits in systematic form the famous contradictions into which, as he notes, reason precipitates itself when it asks metaphysical questions. Kant is enormously impressed by the discovery of these contradictions, and it is regrettable only that he does not sufficiently discuss their formal character or illustrate them with genuine examples.

The only way to avoid these antinomies, in Kant’s opinion, is to adopt his own (critical) point of view and recognize that the world that is the object of our knowledge is a world of appearances, existing only insofar as it is constructed; this solution enables us to dismiss both parties to the dispute in the case of the first two antinomies, and to accept the contentions of both parties in the case of the other two. If the world exists only insofar as it is constructed, it is neither finite nor infinite but indefinitely extensible and so neither has nor lacks a limit in space and time. Equally, if the world is phenomenal we have at least the idea of a world that is not phenomenal; and natural causality can apply without restriction to the first without precluding the application of a different type of causality to the second. This is admittedly only an empty hypothesis so far as theoretical reason is concerned, but Kant argues that it can be converted into something more satisfactory if we take account of the activities of practical (moral) reason.

**THE EXISTENCE OF GOD.** The fourth antinomy is concerned with God’s existence. Kant’s full treatment of the subject is not in the section on the antinomies but in that headed “The Ideal of Pure Reason,” the locus classicus for Kant’s criticisms of speculative theology. These criticisms have proved as devastating as those he brought against rational psychology.

*Speculative proofs.* There are, Kant argues, only three ways of proving God's existence on the speculative plane. First, we can proceed entirely a priori and maintain that the very idea of God is such that God could not *not* exist; this is the method of the Ontological Argument. Second, we can move from the bare fact that the world exists to the position that God is its ultimate cause, as in the First Cause, or Cosmological, Argument. Finally, we can base our contention on the particular constitution of the world, as in the "physicotheological proof" (the Argument from Design).

Kant argues that all three types of proof are fallacious. The Ontological Argument fails because it treats existence as if it were a "real predicate," whereas "it is not a concept of something which could be added to the concept of a thing. It is merely the positing of a thing, or of certain determinations, as existing in themselves" (B 626). The First Cause Argument fails on several counts: because it uses the category of cause without realizing that only in the schematized form is the category significant; because it assumes that the only way to avoid an actually infinite causal series in the world is to posit a first cause; finally and most important, because it presupposes the validity of the Ontological Proof, in the step which identifies the "necessary being" or First Cause with God. The Argument from Design makes all these mistakes and some of its own, for even on its own terms it proves only the existence of an architect of the universe, not of a creator, and such an architect would possess remarkable but not infinite powers.

*The moral proof.* In spite of Kant's criticisms of the classical arguments for God's existence, he is neither an atheist nor even a believer in the principle of *credo quia impossibile*. He both believes in God and holds that the belief can be rationally justified. For although speculative theology is, broadly, a tissue of errors, moral theology is perfectly possible. But the moral proof of God's existence differs from the attempted speculative proofs in at least two significant respects. First, it begins neither from a concept nor from a fact about the world, but from an immediately experienced moral situation. The moral agent feels called upon to achieve certain results, in particular to bring about a state of affairs in which happiness is proportioned to virtue, and knows that he cannot do it by his own unaided efforts; insofar as he commits himself to action he shows his belief in a moral author of the universe. Affirmation of God's existence is intimately linked with practice; it is most definitely not the result of mere speculation. Again, a proof like the First Cause Argument claims universal validity; standing as it does on purely

intellectual grounds it ought, if cogent, to persuade saint and sinner alike. But the moral proof as Kant states it would not even have meaning to a man who is unconscious of moral obligations; the very word *God*, removed from the moral context that gives it life, is almost or quite without significance. Accordingly Kant states that the result of this proof is not objective knowledge but a species of personal conviction, embodying not logical but moral certainty. He adds that "I must not even say '*It is morally certain that there is a God ...*,' but '*I am morally certain*'" (B 857). In other words, the belief or faith Kant proposes as a replacement for discredited metaphysical knowledge can be neither strictly communicated nor learned from another. It is something that has to be achieved by every man for himself.

## ETHICS

Kant perhaps intended originally to make the *Critique of Pure Reason* the vehicle of his entire philosophy, but it was clear before he completed it that some of his views, especially those on ethics, could be only touched on there. In the years immediately following its publication he displayed exceptional energy in defending and restating the theories he had already put forth and in extending his philosophy to cover topics he had hitherto not treated, or not treated in detail. By 1788 he had not only published the second, substantially revised edition of the *Critique of Pure Reason*, but had laid the foundations for his ethics in his short but influential *Groundwork of the Metaphysics of Morals* (1785) and had undertaken a more elaborate survey of moral concepts and assumptions in the *Critique of Practical Reason* (1788). He had also, in passing, written his essay *Metaphysical Foundations of Natural Science* (1786), intended as a first step toward a projected but never completed metaphysics of nature. Two years after the *Critique of Practical Reason* he produced yet another substantial work, the *Critique of Judgment*, in which he expressed his views on, among other topics, aesthetics and teleology.

**MORAL ACTIONS.** If he had published nothing else but the *Groundwork of the Metaphysics of Morals* Kant would be assured a place in the history of philosophy. Difficult as it is to interpret in some of its details, this work is written with an eloquence, depth of insight, and strength of feeling that make an immediate impact on the reader and put it among the classics of the subject. Kant says that his "sole aim" in the book is "to seek out and establish *the supreme principle of morality*." He wishes to delineate the basic features of the situation in which moral decisions

are made, and so to clarify the special character of such decisions.

The situation as he sees it is roughly as follows. Man is a creature who is half sensual, half rational. Sensuous impulses are the determining factor in many of his actions, and the role of reason in these cases is that assigned to it by Hume; it is the slave or servant of the passions. But there is an identifiable class of actions in which reason plays a different part, leading rather than following. This is the class of moral actions. Such actions have the distinguishing feature that they are undertaken not for some ulterior end, but simply because of the principle they embody.

**INTENTIONS AND MORAL JUDGMENTS.** The moral worth of an action, as Kant puts it (*Grundlegung*, 2nd ed., p. 13), lies “not in the purpose to be attained by it, but in the maxim in accordance with which it is decided upon.” Whether or not I attain my ends does not depend on me alone, and my actions cannot be pronounced good or bad according to the effects they actually bring about. But I can be praised or blamed for my intentions, and I can, if I choose, make sure that the maxim or subjective principle of my action accords with the requirements of morality. To do this I have only to ask myself the simple question whether I could will that the maxim should become a universal law, governing not merely this particular action of mine, but the actions of all agents similarly circumstanced. For it is a formal property of moral as of scientific judgments, recognized in practice even by the unsophisticated, that they hold without distinction of persons; the result is that an action can be permissible for me only if it is permissible for anyone in my situation.

**PRACTICAL REASON.** There are difficulties in this position of which Kant seems to have been unaware. In particular, he never asks how I am to decide what is the correct description, and hence the maxim, of my act or proposed act. Nor is it obvious how the theory shows the falsity of Hume’s view that “reason alone can never be a motive to any action of the will”—how it can be shown, in Kant’s language, that pure reason really is practical. The practical effectiveness of reason is manifested not in the capacity to reflect, which both Kant and Hume allow, but in the power to originate or inhibit action. Kant obviously thinks that the facts of temptation and resistance to temptation, which he sees as ubiquitous in the moral life, have a clear bearing on the question whether reason really has such a power. Recognition that I ought to follow a certain course of action, whether I want to or not, and that anything that is morally obligatory must also be

practically possible, is enough in his view to show that I am not necessarily at the mercy of my desires. In favorable cases, at any rate (Kant pays too little attention to the factors that diminish and sometimes demolish responsibility), I am free to resist my sensuous impulses and to determine my actions by rational considerations alone.

**CONSEQUENCES OF THE MORAL LAW.** Some commentators have seen Kant as an ethical intuitionist, but this view is clearly mistaken. His “practical reason” is not the faculty of insight into the content of the moral law; it is rather the capacity to act. In determining what the moral law commands, I have initially no other resources at my disposal than the reflection that it must be applied impartially. But in practice this criterion carries others with it. If the moral law applies without distinction of persons, Kant believes it follows that I must treat all human beings as equally entitled to rights under it, and that therefore I must regard them as ends in themselves and never as merely means to my own ends. Further, once I recognize that other people are morally in the same position as I am myself, and that we belong to the same moral community, I recognize both that I can legitimately pursue those of my purposes that do not conflict with the moral law and that I also have a duty to facilitate the like pursuit on the part of my fellows. So though Kant is a formalist in his view of moral reason (as in his view of the theoretical intellect), he sees his ethics as having practical consequences of the first importance. He sets these consequences out in his lectures on ethics and develops them in detail later in his 1797 *Metaphysic of Morals*. To judge him by the *Groundwork* alone, or even by the *Groundwork* and the *Critique of Practical Reason* taken together, is to do less than justice to the scope of his ethical reflection.

**MORAL IMPERATIVES.** Previous moral philosophies, Kant writes, whether they put their stress on moral sense or on moral reason, have all been vitiated by a failure to recognize the principle of the autonomy of the will. Utilitarianism, for instance, is a heteronomous ethical theory because, according to its supporters, the point of a moral action is to promote an end or purpose beyond the action, the greatest happiness of the greatest number. Kant is not unaware of the importance of ends and purposes in actions: In the *Critique of Practical Reason* he corrects the one-sidedness of the *Groundwork* by discoursing at length on the concept of “good” as well as on that of “duty.” But he holds, even so, that consideration of ends cannot be of primary importance for the moral agent, since a moral action is one that is commanded for its own sake, not with a view to some purpose it is

expected to bring about. The imperatives of morality command categorically, unlike those of skill or prudence, which have only hypothetical force. A rule of skill or a counsel of prudence bids us take certain steps if we wish to attain a certain end—good health or overall happiness, for example. There is no “if” about a command of morality; it bids me act in a certain way whether I want to or not, and without regard to any result the action may bring about. It represents a course of conduct as unconditionally necessary, not just necessary because it conduces to a certain end.

**FREEDOM AND NECESSITY.** The concepts of duty, the categorical imperative, the moral law, and the realm of ends (in which we are all at once subjects and lawgivers) are intended by Kant to illuminate the moral situation. But even when we know what that situation is, there are many features of it that remain mysterious. Morality as Kant expounds it involves autonomy of the will, and such autonomy clearly makes no sense except on the supposition of freedom. But how we can think of the will as free and at the same time regard ourselves as subject to the moral law, that is, as under obligation, has still to be explained. To throw light on this question, Kant invokes the concept of the two worlds, the sensible and the intelligible, to which he made appeal in the *Critique of Pure Reason*. Insofar as I exercise the faculty of reason I have to regard myself as belonging to the intelligible world; insofar as I exercise my “lower” faculties I am part of the world of nature, which is known through the senses. Were I a purely rational being, possessed of what Kant sometimes calls a “holy will,” all my actions would be in perfect conformity with the principle of autonomy, and the notions of obligation and the moral law would have no meaning for me. They would similarly have no meaning if I were a purely sensuous being, for then everything I did would occur according to natural necessity, and there would be no sense in thinking that things ought to be otherwise. The peculiarities of the human moral situation arise from the fact that men are, or rather must think of themselves as being, at once intelligible and sensible. Because I regard myself as belonging to the intelligible order, I see myself as “under laws which, being independent of nature, are not empirical but have their ground in reason alone” (*Critique of Practical Reason*, p. 109). But I am also a natural being, and those laws therefore present themselves to me in the form of commands that I acknowledge as absolute because I recognize that the intelligible world is the ground of the sensible. We can thus see “how a categorical imperative is possible.”

What we cannot see, if Kant is to be believed, is how freedom is possible. “All men think of themselves as having a free will. . . . Moreover, for *purposes of action* the footpath of freedom is the only one on which we can make use of reason in our conduct. Hence to argue freedom away is as impossible for the most abstruse philosophy as it is for the most ordinary human reason” (*Critique of Practical Reason*, p. 113–115). Yet freedom remains what it is in the *Critique of Pure Reason*, “only an idea whose objective reality is in itself questionable,” and there is a *prima facie* clash between the claim to freedom and the knowledge that everything in nature is determined by natural necessity. Kant seeks to dissolve the antinomy of freedom and necessity by means of two expedients. First, he insists that the idea of freedom required for morals is not a theoretical but a practical idea. Freedom does not need to be established as a metaphysical fact; it is enough that we find it necessary to act on the assumption that freedom is real, since “every being who cannot act except under the idea of freedom is by this alone—from the practical point of view—really free” (p. 100). The status of the proposition that the will is free is identical with that of the proposition that there is a God. Both are postulates of practical reason—beliefs that we “inevitably” accept; but they are emphatically not items of knowledge in the strict sense of that term. Second, Kant sees no difficulty in our accepting the postulate of freedom, because there is no contradiction in thinking of the will as free. As an object of theoretical scrutiny I must regard myself as a phenomenon; as a moral agent possessed of a will I transfer myself to the intelligible world of noumena. I can be at once under necessity *qua* phenomenon and free *qua* noumenon. But the question of how I can be free leads to the extreme limits of practical philosophy. Freedom cannot be explained, for we lack all insight into the intelligible world; the most we can do is make clear why it cannot be explained. The critical philosophy purports to have performed this task.

**EPISTEMOLOGY AND ETHICS.** Kant advocates a form of nonnaturalist theory in ethics. But neither his ethics nor his theory of knowledge can be fully understood in isolation one from the other. The two together constitute an overall theory that is not so much a metaphysics as a substitute for a metaphysics: A theory that argues that human insight is strictly limited, but urges that, so far from being regrettable, this testifies to “the wise adaptation of man’s cognitive faculties to his practical vocation” (*Critique of Practical Reason and Other Writings*, Beck translation, 1949, p. 247). If we knew more, we might indeed do as we ought, for “God and eternity in their

awful majesty would stand unceasingly before our eyes,” but we should not then do things as a matter of duty, but rather out of fear or hope. And thus the world would be poorer, for we should lose the opportunity to manifest “good will,” the only thing in the world, “or even out of it, which can be taken as good without qualification.”

### THE CRITIQUE OF JUDGMENT

None of Kant’s other writings is as forceful or original as the first two *Critiques* and the *Groundwork*. The *Critique of Judgment* contains some fresh ideas of remarkable power, but it constitutes a series of appendixes or addenda to Kant’s earlier work rather than something wholly new. It should really be seen as three or four separate essays whose connecting link is the concept of purpose.

**SYSTEM OF SCIENCE.** The first essay, the introduction, begins with a pedantic discussion of the status of the power of judgment. It then takes up a problem aired in the appendix to the “Dialectic” in the *Critique of Pure Reason*—the problem of the special assumptions involved in the belief that we can construct a system of scientific laws. If we are to have such a system, Kant argues, we must proceed on the principle that nature is “formally purposive” in respect of empirical laws; that nature is such that we can make sense of it not merely in general, but also in detail. Kant’s object is to show that this principle is not a constitutive principle of things, but simply a subjective maxim of judgment.

In the *Critique of Pure Reason* (B 670ff.) Kant argues for what he calls the regulative employment of the ideas of reason: the use of ideas to order empirical inquiries in such a way that we try at once to find greater and greater diversity of form in the material before us and to group different species and subspecies together under ever higher genera. In actual practice we assume that nature will display the unity-in-diversity required for this program to be carried out, but we cannot prove that it will do so as we can prove that whatever falls within experience will conform to the categories. Hence we are concerned not with objective rules, but only with maxims, defined in this connection as “subjective principles which are derived, not from the constitution of an object but from the interest of reason in respect of a certain possible perfection of the knowledge of the object” (B 694).

In the *Critique of Pure Reason* Kant ascribes these maxims to reason. In the *Critique of Judgment*, he assigns them to judgment, in effect the identical doctrine. The difference is accounted for by two facts. First, by the time

Kant wrote the *Critique of Judgment*, the term *reason* suggested to him nothing but practical reason. Second, he had come to think that if the power of judgment is genuinely separate from understanding on the one hand and reason on the other it must have a priori principles of its own. A division within the power of judgment itself, into determinant and reflective activities, had helped to make this last point plausible, at least in the eyes of its author.

**AESTHETICS.** The “Critique of Aesthetic Judgment,” the first major division of the *Critique of Judgment*, uses the term *aesthetic* in what has become its modern sense. The discussion is Kant’s contribution to the controversies initiated by Lord Shaftesbury and Francis Hutcheson when they made both moral and aesthetic judgments matters of feeling; Kant rejects this view and also explains why he yet cannot approve of Baumgarten’s attempt to “bring the critical treatment of the beautiful under rational principles, and so to raise its rules to the rank of a science” (B 35, note *a*). Kant needs to show, for the purposes of his general philosophy, that aesthetic judgments are essentially different from moral judgments on the one hand and scientific judgments on the other. This need apart, he had a long-standing independent interest in the subject; in 1764, thirty years before the *Critique of Judgment*, he published an essay on the beautiful and the sublime (*Beobachtung über das Gefühl des Schönen und Erhabenen*, Königsberg). Such an interest may seem surprising in view of the obvious limitations of Kant’s own aesthetic experience; he had some feeling for literature, especially for satire, but little or no real knowledge of either painting or music. But what he has in mind in discussing the beautiful is the beauty of nature as much as anything, and his main interest is not in making aesthetic judgments, but in deciding on their logical status.

Judgments of taste, as Kant calls them, are peculiar in that they not only rest on feeling but also claim universal validity. That they rest on feeling seems to him obvious: When I ascribe beauty to an object or scene I do so not because I have observed some special character in it, but because contemplation of its form gives me immediate delight. But it is an entirely disinterested form of delight, quite different from that we feel concerning things that are agreeable, or even things that are good. When we take pleasure in something beautiful we are not desiring to possess it, or indeed taking up any attitude toward its existence. The fact that aesthetic delight is disinterested allows us to think of it as universally shared:

Since the delight is not based on any inclination of the subject (or any other deliberate interest), but the Subject feels himself completely free in

respect to the liking which he accords to the object, he can find as reason for his delight no personal conditions to which his own subjective self might alone be party. Hence he must regard it as resting on what he may also presuppose in every other person; and therefore he must believe that he has reason for demanding a similar delight from every one. (*Critique of Judgment*, Meredith translation, Sec. 6)

Because they claim universal validity, judgments of taste appear to rest on concepts, but to think that they do is a mistake. The universality attaching to judgments of taste is not objective but subjective; to explain it we must refer to “nothing else than the mental state present in the free play of imagination and understanding (so far as these are in mutual accord, as is requisite for *cognition in general*)” (Sec. 9). As in the *Critique of Pure Reason*, Kant argues that both imagination and understanding are involved in the apprehension of any spatiotemporal object but that when we simply contemplate any such object aesthetically, no definite concept is adduced; and so the two faculties are in free play. It is the harmony between the faculties in any act of aesthetic contemplation that Kant takes to be universally communicable, and believes to be the basis for the pleasure we feel.

In addition to analyzing judgments about the beautiful, Kant devoted considerable attention in the *Critique of Judgment* to another concept which figured prominently in the aesthetics of his day, that of the sublime. Burke and others had given what was in effect a psychological description of the conditions in which we judge, say, the sight of a mountain range or a storm at sea to be sublime. Kant was all the more anxious to specify more exactly the meaning of such judgments and to establish their transcendental conditions because he was convinced that we here also have to do with a feeling that is held to be universally communicable. The feeling for the sublime, as he explained it, is connected not with the understanding, as is that for the beautiful, but with reason. To put his view somewhat crudely, we are at first abashed by the formlessness of some parts of nature, only to be elevated when we reflect on the utter inadequacy of these objects to measure up to our own ideas, and in particular to our moral ideas. Thus the sublime is not, as might at first sight be supposed, a quality which inheres in natural objects, but a feeling which the contemplation of natural objects provokes in us. It could have no existence for a being totally lacking in culture (a savage might feel fear on observing “thunderclouds piled up the vault of heaven,” to use one of Kant’s own examples, but could

not recognize their sublimity), yet it is not a mere product of culture or social convention. “Rather is it in human nature that its foundations are laid, and, in fact, in that which, at once with common understanding, we may expect everyone to possess and may require of him, namely, a native capacity for the feeling for (practical) ideas, that is, for moral feeling” (Sec. 29).

TELEOLOGY. One of Kant’s motives for wanting to avoid making beauty an objective characteristic was that he thought such a view would lend force to the Argument from Design, and so encourage the revival of speculative theology. If things could be said to possess beauty in the same sort of way in which they possess weight, it would be a short step to talking about the Great Artificer who made them to delight us. Arguments of the same general kind were still more vividly present to his mind when he came to write the second main section of the *Critique of Judgment*, the “Critique of Teleological Judgment.” Indeed, he ended the book with a lengthy section that underlines yet again the shortcomings of “physicotheology” and points up the merits of “ethicotheology.”

Before confronting theology directly, Kant embarked on a detailed and penetrating discussion of the nature and use of teleological concepts. The existence of organic bodies, he argues, is something for which we cannot account satisfactorily by the mechanical principles sanctioned by the physical sciences; to deal with organic bodies we must employ a distinct principle, the principle of teleology, which can do justice to the fact that “*an organized natural product is one in which every part is reciprocally both means and end*” (Sec. 66). Such a principle cannot be used for cognitive purposes in the strict sense; it can be employed only by reflective judgment to guide “our investigation of ... [organic bodies] by a remote analogy with our own causality according to ends generally, and as a basis for reflection upon their supreme source” (Sec. 65). Teleology is a concept that occupies an uneasy intermediate position between natural science and theology. We cannot help using it to describe the world about us, yet we cannot assign to it full scientific status. Kant mitigates the austerities of this position by suggesting in his section “The Antinomy of Judgment” that in the end the mechanical and teleological principles stand on the same level, both belonging to reflective judgment. But it is hard to see how this can be made consistent with the doctrines of the *Critique of Pure Reason*, which ascribes constitutive force to the concepts of “pure physics,” or even with the distinction in the *Critique of Judgment* itself between explaining something and merely “making an estimate” of it. We use the categories to

explain, but can employ teleological concepts only for the purpose of making an estimate. Kant's underlying attitude to the whole question is revealed most clearly in the passage at the end of Sec. 68 of the *Critique of Judgment*, where he asks why teleology "does not ... form a special part of theoretical natural science, but is relegated to theology by way of a propaedeutic or transition." He answers:

This is done in order to keep the study of the mechanical aspect of nature in close adherence to what we are able so to subject to our observation or experiment that we could ourselves produce it like nature, or at least produce it according to similar laws. For we have complete insight only into what we can make and accomplish according to our conceptions. But to effect by means of art a presentation similar to organization, as an intrinsic end of nature, infinitely surpasses all our powers. (Meredith translation)

It would be interesting to know if Kant would say the same were he alive today.

#### OTHER PHILOSOPHICAL WRITINGS

After publishing the three *Critiques*—Kant was sixty-six when the *Critique of Judgment* appeared—he continued to publish essays and treatises on a wide variety of philosophical subjects. Most of these are in fact contributions to applied philosophy, for he took the view that scientific inquiries and practical activities alike stand in need of philosophical foundations. In many cases he attempts to supply these foundations by means of the principles established in his main works—hence the general shape of his philosophies of science and religion, and of his political philosophy. It would, however, be wrong to see these as no more than mechanical applications of general Kantian conclusions. For although Kant was deeply and indeed unduly devoted to system, he also had a wide and in some cases penetrating knowledge of many different branches of learning and human activity, and there are few philosophical topics that he touches without illuminating; in fact, Kant gave the names still in use to most of the branches of applied philosophy he took up.

**PHILOSOPHY OF NATURE.** In the preface to his *Metaphysical Foundations of Natural Science*, Kant argues that the very concept of scientific knowledge is such that we can use the term properly only when dealing with truths that are both apodictically certain and systematically connected. A discipline that is thoroughly and entirely empirical cannot comply with these requirements; hence

Kant pronounces chemistry to be no better than "systematic art or experimental doctrine." But the situation is different in physics. Although Kant was as firmly persuaded as any empiricist that detailed knowledge of the physical world could be arrived at only by observation and experiment, he was also sure that physics has an unshakable a priori basis that makes it worthy of the name of science. It owes this, in Kant's judgment, to the fact that its fundamental concepts are capable of mathematical expression, as those of chemistry are not, and to the close connection of these concepts with the categories, the basic concepts of rational thought.

The main object of the *Metaphysical Foundations* is to demonstrate the second of these points by means of an examination of the idea of matter. Starting from what professes to be an empirically derived definition of matter, "that which is capable of movement in space," Kant proceeds to a deduction of its main properties in the light of the table of categories. The result is, in effect, a rereading or reinterpretation of then-current physical theory in which all the main doctrines of Newton find their place, but which is distinctive in that the atomism professed by many physicists of the day is rejected in favor of a dynamical theory of matter resembling that of Leibniz. Kant argues in the *Critique of Pure Reason* that only mistaken metaphysics leads scientists to think they must accept the notions of absolutely homogeneous matter and absolutely empty space. In the *Metaphysical Foundations* he works out an alternative conception of matter in terms of moving forces, omnipresent but varying in degree, and puts it forward as both theoretically satisfactory and consistent with the empirical findings.

It is difficult not to see in these views the beginnings of *Naturphilosophie* as it was to be practiced by Schelling and G. W. F. Hegel, the more so if we read the *Metaphysical Foundations* in the light of Kant's further treatment of the subject in the notes published as *Opus Postumum*. But in 1786 at any rate Kant was still far from committing the extravagances of the speculative philosophers of nature. For one thing, he was both more knowledgeable about and more respectful of the actual achievements of physical scientists than were his romantic successors, doubtless because, unlike them, he was something of a physical scientist himself. For another, the lesson he drew from his 1786 inquiries was not how much physical knowledge we can arrive at by the use of pure reason, but how little. To establish the metaphysical foundations of natural science was a useful task, but it was in no sense a substitute for empirical investigation. Despite these differences from *Naturphilosophie*, it must be allowed that *Metaphysical*

*Foundations* testifies, in name as well as in content, to the extent of Kant's commitment to rationalism (his theory of science could scarcely be further from Hume's) and to the way in which he was at least tempted by the constructivism favored by some of his younger contemporaries.

**PHILOSOPHY OF HISTORY.** Although Kant was quite unaware of the problems about historical knowledge and explanation with which philosophers since Wilhelm Dilthey have dealt, he made an important and characteristic contribution to speculative philosophy of history in his essay "Idee zu einer allgemeinen Geschichte in Weltbürgerlicher Absicht" (Idea of a Universal History from a Cosmopolitan Point of View; *Berliner Monatsschrift*, November 1784, 386–410). Observing that the actions of men, when looked at individually, add up to nothing significant, he suggests that nature or providence may be pursuing through these actions a long-term plan of which the agents are unaware. To see what the plan may be we have to reflect on two points: First, that nature would scarcely have implanted capacities in human beings if she had not meant them to be developed, and second, that many human intellectual capacities (for example, the talent for invention) are such that they cannot be satisfactorily developed in the lifetime of a single individual.

The development of such capacities belongs to the history of the species as a whole. Kant suggests that the hidden plan of nature in history may well be to provide conditions in which such capacities are more and more developed, so that men move from barbarism to culture and thus convert "a social union originating in pathological needs into a moral whole." The mechanism of the process lies in what Kant calls the "unsocial sociability" of human beings—the fact that they need each other's society and help and are nevertheless by nature individualists and egotists—which ensures that men develop their talents to the maximum extent, if only to get the better of their fellows, and at the same time necessitates man's eventually arriving at a form of civil society that allows for peaceful rivalry under a strict rule of law. But such a "republican" constitution would be of no value unless it had its counterpart in the international sphere, for the struggles of individuals against one another are paralleled by the struggles of states. We must accordingly conclude that the final purpose of nature in history is to produce an international society consisting of a league of nations, in which war is outlawed and the way is finally clear for peaceful competition between individuals and nations.

The difficulty with this as with other lines of Kant's thought is to understand its relation to empirical inquiries. From what Kant says it seems clear that he intended "philosophical" history to be an alternative to history of the everyday kind, not a substitute for it. Nor did he pretend to be writing philosophical history himself; his essay merely puts forward the idea of or offers a "clue" to, such a history, leaving it to nature to produce someone really capable of making sense of the historical facts as Johannes Kepler and Newton made sense of physical facts. It is difficult to see, even so, how Kant could have possessed the idea of history as meaningful without knowing the facts, or alternatively how he could know that the idea throws light on the facts when it was discovered without any reference to them.

**PHILOSOPHY OF LAW AND POLITICS.** Kant's views about law and politics, like his philosophy of history, are obviously tied up with his ethics. Kant holds that legal obligations are a subspecies of moral obligation; thus the rational will, and neither force nor the commands of God, is the basis of the law. His standpoint in philosophy of law is thus broadly liberal, though his attitude on many particular legal issues is far from liberal as the term is now understood. He holds, for instance, that if one of the partners to a marriage runs away or takes another partner, "the other is entitled, at any time, and incontestably, to bring such a one back to the former relation, as if that person were a thing" (*Metaphysic of Morals*, Sec. 25). He is notorious as a strong supporter of the retributive theory of punishment and an uncompromising advocate of the death penalty for murder. The explanation of his harshness in these matters is to be found in his legalistic approach to ethics, which leaves little room for sympathy or forgiveness.

In politics also Kant combines a fundamentally liberal attitude with specific views that are conservative, if not reactionary. Following Rousseau, he attempts to explain political authority partly in terms of the general will and partly in terms of the original contract. Insofar as he insists on the contract, which he interprets not as a historical fact but as a regulative idea, he is advocating a version of political liberalism which lays particular emphasis on the rule of law; insofar as he grounds supreme political authority in the will of the people as a whole, he is obviously flirting with more radical doctrines—from whose consequences he is quick to draw back. An admirer of the French Revolution, he nevertheless denies that the subjects of the most ill-governed states have any right of rebellion against their rulers. And though the mixed constitution he favors is one in which citizens can make their

voices heard through their representatives, he is for confining the franchise to persons who possess “independence or self-sufficiency,” thus excluding from “active” citizenship (according to Sec. 46 of the *Metaphysic of Morals*) apprentices, servants, woodcutters, plowmen, and, surprisingly, resident tutors, as well as “all women.” The truth is, however, that Kant’s political theorizing was done in a vacuum; in his day there was no real chance for a Prussian professor of philosophy to influence political events.

**PHILOSOPHY OF RELIGION.** In the sphere of religion the views of a professor of philosophy could be influential, and Kant’s views on this subject were certainly provocative. He treats religion as essentially, if not quite exclusively, a matter of purity of heart—thus dispensing with speculative theology altogether and assigning a meager importance to the institutional side of religion. To adopt the religious attitude, as Kant sees it, is to look on duties as if they were divine commands. But this, he explains, is only to insist on the unconditioned character, the ineluctability, of moral obligation; it is a way of representing morality, not a way of going beyond it. Knowledge of the supersensible, as Kant thought he had shown in the *Critique of Pure Reason*, is impossible; and although moral practice carries with it belief in God and a future life, the whole meaning and force of that belief is to be found in a persistence in moral endeavor and a determination to repair moral shortcomings. The pure religion of morality needs no dogma apart from these two fundamental articles of belief, which are accessible immediately to the simplest intelligence. Still less has it any need of the external trappings of religion—priests, ceremonies, and the like—although the body of believers must think of themselves as belonging to a church, universal but invisible, and the practices of visible churches sometimes serve to stimulate or strengthen moral effort, in a way which is useful but not indispensable.

The religion of morality is on this account a religion of all good men. Despite this, Kant took a particular interest in Christianity, which he saw as at least approximating true religion though corrupted by the presence of extraneous elements derived from Judaism. His book *Religion within the Bounds of Mere Reason* (1793) is in effect a commentary on and a reinterpretation of Christian doctrine and practice, written with the object of making this conclusion clear. In this reinterpretation the doctrine of original sin is transformed into a doctrine of the radical evil in human nature, which is the positive source of moral failing; and that of the Incarnation is replaced by an account of the triumph of the good prin-

ciple over the bad, the part of the historical Jesus being taken by an idea of reason, that of man in his moral perfection. Kant sets aside the historical elements in Christianity as having no importance in themselves: Whatever is true in the religion must be derivable from moral reason. To think of the uttering of religious formulas or the performance of formal services to God as having a value of their own is to fall into the grossest superstition. It is perhaps scarcely surprising that these sentiments, whose attraction for youth can be seen in Hegel’s *Jugend-schriften*, should have struck the Prussian authorities as subversive and led the orthodox King Frederick William II to demand that Kant refrain from further pronouncements on religion. Though Kant, in his letter acceding to this demand, protested that he had no thought of criticizing Christianity in writing his book, it is hard to take his protest quite seriously, for he had certainly meant to suggest that many of the beliefs and actions of practicing Christians were without value, if not positively immoral. Indeed, the originality and continuing interest of his work on religion connect directly with that fact.

**THE OPUS POSTUMUM.** In the last years of his life—from about 1795 on—Kant was engaged in the composition of what would have been a substantial philosophical work; the preparatory notes for it have been published as *Opus Postumum*. Its original title was “Transition from Metaphysical Foundations of Natural Science to Physics,” and in its original form its object was to carry further the process, begun in 1786 in the *Metaphysical Foundations of Natural Science*, of finding an a priori basis for physics. No longer content with the formal structure for which he had argued earlier, Kant thought he had to show that some of the particular laws of nature could be known in advance of experience. The broadest types of physical possibility were determined by the constitution of the human mind; it was this, for example, which explained the presence in nature of just so many fundamental forces, and even of an omnipresent ether.

These speculations about the foundations of physics led Kant to epistemological considerations of a wider kind. The whole subject of the relation of the form of experience to its matter, with the question how far the form shapes the matter, arose in his mind anew, doubtless because of the criticisms directed against the formalist position of the *Critique of Pure Reason* by self-professed disciples such as Fichte. In 1799 Kant dissociated himself publicly from the views expressed in Fichte’s *Wissenschaftslehre*, according to which the subject of knowledge “posits” the objective world and so, in a way, creates nature. Yet the evidence of the *Opus Postumum* is that at

this time, or shortly thereafter, Kant was toying with similar ideas and was even using some of the same vocabulary. It is perhaps fortunate for Kant's reputation that he was not able to get his final philosophical thoughts into publishable form.

## Bibliography

### WORKS BY KANT

#### Collected Works

*Gesammelte Schriften*. 23 vols., edited under the supervision of the Berlin Academy of Sciences. Berlin: Reimer, 1902–1955. The standard collected edition of Kant's writings; contains his correspondence and hitherto unpublished notes (including those for the *Opus Postumum*) as well as everything he published. Further volumes covering Kant's lectures are in preparation.

*Kants Werke*. 10 vols, edited by Ernst Cassirer. Berlin: Cassirer, 1912–1922. Contains the published works, with full indications of the contents of the original editions.

Philosophische Bibliothek series. Leipzig and Hamburg, 1904–. Separately bound editions of all the treatises listed below under the head "Main Treatises," with useful introductions; also includes *Kleinere Schriften zur Geschichtsphilosophie, Ethik, und Politik*.

#### Main Treatises

*Allgemeine Naturgeschichte und Theorie des Himmels*. Königsberg and Leipzig, 1755. English translation by W. Hastie in *Kant's Cosmogony* (Glasgow, 1900).

*Der einzig mögliche Beweisgrund zu einer Demonstration des Daseins Gottes*. Königsberg, 1763. No serviceable translation.

*Träume eines Geistersehers, erläutert durch Träume der Metaphysik*. Königsberg, 1766. Translated by E. F. Goerwitz into English as *Dreams of Spirit-Seer* (New York, 1900).

*De Mundi Sensibilis atque Intelligibilis Forma et Principiis Dissertatio*. Königsberg, 1770. Translated into English in Handside's *Kant's Inaugural Dissertation and Early Writings on Space* (Chicago: Open Court, 1929).

*Kritik der reinen Vernunft*. Riga, 1781; 2nd ed., Riga, 1787. The first edition is customarily referred to as A, the second edition as B. The most useful modern edition is by Raymond Schmidt (Leipzig, 1926). There are English translations by Francis Heywood (London, 1838); J. M. D. Meiklejohn (London, 1854), F. Max Müller (2 vols., London, 1881), and N. Kemp Smith (London Macmillan, 1929). Kemp Smith's version is the fullest and most reliable.

*Prolegomena zu einer jeden künftigen Metaphysik die als Wissenschaft auftreten können*. Riga, 1783. English translations are available by John Richardson (*Prolegomena to Future Metaphysics*, in *Metaphysical Works of the Celebrated Immanuel Kant*, London, 1836), J. P. Mahaffy and J. H. Bernard (*The Prolegomena*, London, 1872), E. B. Bax (*Kant's Prolegomena and Metaphysical Foundations of Natural Science*, London, 1883), Paul Carus (*Prolegomena to Any Future Metaphysics*, Chicago, 1902), L. W. Beck (same title as Carus's, New York: Liberal Arts Press, 1951), and P. G. Lucas (same title as Carus's, Manchester, U.K., 1953). The Beck and Lucas translations are much the best.

*Grundlegung zur Metaphysik der Sitten*. Riga, 1785; 2nd ed., Riga, 1786. Translated into English by T. K. Abbott as *Fundamental Principles of the Metaphysics of Morals* (in *Kant's Critique of Practical Reason and Other Works on the Theory of Ethics*, London, 1873), by L. W. Beck as *Foundations of the Metaphysics of Morals* (in *Critique of Practical Reason and Other Writings in Moral Philosophy*, Chicago: University of Chicago Press, 1949), by H. J. Paton (from the 2nd edition) as *The Moral Law, or Kant's Groundwork of the Metaphysics of Morals* (London: Hutchinson, 1948). All three versions are good; Paton's is the most elegant. Quotations in the text of this article are from Paton's translation; the citations to page numbers in the 2nd edition are taken from Paton's marginal notation.

*Metaphysische Anfangsgründe der Naturwissenschaft*. Riga, 1786. Translated into English by E. B. Bax (in *Kant's Prolegomena and Metaphysical Foundations of Natural Science*, London, 1883).

*Kritik der praktischen Vernunft*. Riga, 1788. Translated into English by T. K. Abbott, and also by L. W. Beck, as *Critique of Practical Reason* in the books cited for the *Grundlegung zur Metaphysik der Sitten*. The Beck translation is accurate but somewhat clumsy; it has been published separately (New York, 1956).

*Kritik der Urteilkraft*. Berlin and Liebau, 1790. Translated into English by J. H. Bernard as *Kritik of Judgement* (London, 1892; later reprinted as *Critique of Judgement*). Also translated by J. C. Meredith in two parts, *Critique of Aesthetic Judgement* (Oxford, 1911) and *Critique of Teleological Judgement* (Oxford, 1928), which were reissued together as *The Critique of Judgement* (Oxford: Clarendon Press, 1952). Both the Bernard and the Meredith versions are of poor quality; Meredith's is slightly the better. Kant wrote an introduction to the *Kritik* that he discarded; it is available as *Erste Einleitung in die Kritik der Urteilkraft*, Vol. V, *Kants Werke* (Berlin, 1922), and in English translation by H. Kabir as *Immanuel Kant on Philosophy in General* (Calcutta: Calcutta University Press, 1935).

*Die Religion innerhalb der Grenzen der blossen Vernunft*. First part published separately, Berlin, 1792; published complete at Königsberg, 1793. Translated into English by John Richardson as *Religion within the Sphere of Naked Reason* (in

*Essays and Treatises*, London, 1798), by J. W. Semple as *Religion within the Boundary of Pure Reason* (Edinburgh, 1838), T. M. Greene and H. H. Hudson as *Religion within the Limits of Reason Alone* (Chicago: Open Court, 1934; 2nd ed., with new matter by J. R. Silber, New York: Harper, 1960). The 1960 edition (Greene-Hudson-Silber) is the best.

*Zum ewigen Frieden: ein philosophischer Entwurf*. Königsberg, 1795. The two best English translations are L. W. Beck's *Perpetual Peace* (in *Critique of Practical Reason and Other Writings in Moral Philosophy*, Chicago, 1949; separately bound, New York, 1957) and C. J. Friedrich's *Inevitable Peace* (New Haven, CT, 1948).

*Metaphysik der Sitten*, Part I, *Metaphysische Anfangsgründe der Rechtslehre*; Part II, *Metaphysische Anfangsgründe der Tugendlehre*. Separately bound, Königsberg, 1797. Part I translated into English by W. Hastie as *Kant's Philosophy of Law* (Edinburgh, 1887). Part II translated into English by James Ellington as *Metaphysical Principles of Virtue* (Indianapolis, 1964) and by Mary Gregor as *The Doctrine of Virtue* (New York: Harper and Row, 1964).

*Anthropologie in pragmatischer Hinsicht*. Königsberg, 1798. No English translation.

*Eine Vorlesung über Ethik*, edited from student's notes by P. Menzer. Berlin, 1924. Translated into English by Louis Infield as *Lectures on Ethics* (London: Methuen, 1930).

*Kant on History*. Indianapolis, 1963. Translations by L. W. Beck, R. E. Anchor, and E. L. Fackenheim; contains Kant's minor essays on philosophy of history.

#### WORKS ON KANT

##### Life

The main sources for Kant's life, apart from his letters, are three memoirs published in Königsberg in 1804: L. E. Borowski's *Darstellung des Lebens und Characters Immanuel Kants*; R. B. Jachmann's *Immanuel Kant, geschildert in Briefen an einen Freund*; and E. A. C. Wasianski's *Immanuel Kant in seinen letzten Lebensjahren*. Wasianski's memoir is extensively used in Thomas De Quincey's "The Last Days of Kant" (*Works*, Vol. XII). See also Ernst Cassirer's *Kants Leben und Lehre* (Berlin, 1921), and for a useful short life Karl Vorländer's *Immanuel Kants Leben* (Leipzig, 1911).

##### Commentaries

Rudolf Eisler's *Kantlexicon* (Berlin, 1930) and Heinrich Ratke's *Systematisches Handlexicon zu Kants Kritik der reinen Vernunft* (Leipzig, 1929) are valuable aids to the Kantian student. The periodical *Kantstudien* has published many important contributions to Kantian scholarship and discussion.

For commentaries on the *Critique of Pure Reason*, see Hans Vaihinger, *Kommentar zur Kritik der reinen Vernunft*, 2 vols. (Stuttgart: Spemann, 1881–1892), which covers the opening sections only; N. Kemp Smith, *A Commentary to Kant's Critique of Pure Reason* (London: Macmillan, 1918; rev. ed., 1923), which is strongly influenced by Vaihinger's "patchwork" theory; H. J. Paton, *Kant's Metaphysics of Experience*, 2 vols. (London: Allen and Unwin, 1936), which covers the first half only and is sharply critical of Kemp Smith; A. C. Ewing, *A Short Commentary on Kant's Critique of Pure Reason* (London: Methuen, 1938). T. D. Weldon, *Kant's Critique of Pure Reason* (Oxford, 1945; 2nd ed., Oxford: Clarendon Press, 1958).

On the theory of knowledge see also H. A. Prichard, *Kant's Theory of Knowledge* (Oxford: Clarendon Press, 1909); A. C. Ewing, *Kant's Treatment of Causality* (London: K. Paul, Trench, Trubner, 1924); W. H. Walsh, *Reason and Experience* (Oxford: Clarendon Press, 1947); Graham Bird, *Kant's Theory of Knowledge* (London: Routledge and Paul, 1962); R. P. Wolff, *Kant's Theory of Mental Activity* (Cambridge, MA: Harvard University Press, 1963).

For commentaries on the *Critique of Practical Reason* and other works on ethics, see L. W. Beck, *A Commentary on Kant's Critique of Practical Reason* (Chicago, 1960), a good source; H. J. Paton, *The Categorical Imperative* (London: Hutchinson, 1947), a detailed commentary on the *Grundlegung*; W. D. Ross, *Kant's Ethical Theory* (Oxford, 1954); A. R. C. Duncan, *Practical Reason and Morality* (Edinburgh, 1957); M. J. Gregor, *Laws of Freedom* (Oxford: Blackwell, 1963), which expounds the *Metaphysics of Morals*; P. A. Schilpp, *Kant's Pre-Critical Ethics* (Evanston, IL: Northwestern University, 1938), A. E. Teale, *Kantian Ethics* (London: Oxford University Press, 1951).

For commentaries on the *Critique of Judgment*, see Konrad Marc-Wogau, *Vier Studien zu Kants Kritik der Urteilskraft* (Uppsala, Sweden, 1938); H. W. Cassirer, *A Commentary on Kant's Critique of Judgment* (London: Methuen, 1938).

Commentaries on other aspects of Kant's thought are also available. On the precritical writings, see Giorgio Tonelli, *Elementi metafisici e metodologici in Kant precritico* (Turin, 1959). On Kant's philosophy of religion, see C. C. J. Webb, *Kant's Philosophy of Religion* (Oxford: Clarendon Press, 1926) and F. E. England, *Kant's Conception of God* (London: Allen and Unwin, 1929). On Kant's philosophy of history, see Klaus Weyand, *Kants Geschichtsphilosophie* (Cologne: Cologne University Press, 1964). On Kant as a scientist, see Erich Adickes, *Kant als Naturforscher*, 2 vols. (Berlin, 1924–1925). On the *Opus Postumum*, see Erich Adickes, *Kants Opus Postumum dargestellt und beurteilt* (Berlin, 1920).

##### General Studies

S. Körner, *Kant* (Harmondsworth, U.K., 1955) is the best general introduction; see also G. J. Warnock's chapter in *A Critical History of Western Philosophy*, edited by D. J. O'Connor (New York: Free Press of Glencoe, 1964).

Edward Caird, *The Critical Philosophy of Kant*, 2 vols. (Glasgow, 1889), criticizes Kant from the Hegelian position. Martin Heidegger, *Kant und das Problem der Metaphysik* (Bonn: Cohen, 1929) examines Kant as an "ontologist." H. J. de Vleeschauwer, *La déduction transcendentale dans l'oeuvre de Kant*, 3 vols. (Antwerp, 1934–1937), presents an exhaustive survey of Kant's writings on the problem; de Vleeschauwer offers a one-volume summary in *L'évolution de la pensée kantienne* (Paris, 1939), which has been translated into English by A. R. C. Duncan as *The Development of Kantian Thought* (London: Nelson, 1962). Gottfried Martin, *Immanuel Kant, Ontologie und Wissenschaftstheorie* (Cologne, 1951), translated into English by P. G. Lucas as *Kant's Metaphysics and Theory of Science* (Manchester, U.K.: Manchester University Press, 1955), is influenced but not dominated by Heidegger. Richard Kroner, *Kants Weltanschauung* (Tübingen, 1914), translated into English by J. E. Smith as *Kant's Weltanschauung* (Chicago: University of Chicago Press, 1956), stresses Kant's emphasis on the practical. R. Daval, *La métaphysique de*

*Kant* (Paris: Presses Universitaires de France, 1951), presents “schematism” as the key idea in Kant’s thought.

KANT, IMMANUEL  
[ADDENDUM]

Immanuel Kant’s philosophy continues to exercise significant influence on philosophical developments and generates an ever-growing body of scholarly literature. Work on Kant has progressed in two main directions. Central doctrines of the *Critique of Pure Reason* have been reconstructed, examined, and revised in the light of current philosophical concerns and standards; and the focus of scholarship has widened to include aspects and parts of Kant’s work hitherto neglected, especially in the areas of ethics, aesthetics, philosophy of history, political philosophy, anthropology, and philosophy of science.

## THE CRITIQUE OF PURE REASON

Further advances in interpreting the first *Critique* have occurred in three related areas: the nature and validity of Kant's overall argumentative procedure, with special emphasis on the deduction of the categories; the meaning and function of transcendental idealism and the associated distinction between things in themselves and appearances; and the role of mental activity in Kant's theory of experience.

The deduction of the categories, in which Kant sought to identify and justify the basic concepts underlying all experience and its objects, has become the center of major interpretive efforts. Stimulated by the neo-Kantian analytic metaphysics of Peter F. Strawson, philosophers have attempted to distill a type of argument from Kant's text that refutes skeptical doubts about the reality of the external world and other minds by showing how the skeptical challenge tacitly and unavoidably assumes the truth of the very assumptions it sets out to deny, namely, the reality of external objects and other minds.

While the force of such *transcendental arguments* remains controversial, the analytic–reconstructive approach to the deduction of the categories has also resulted in more textually based interpretations that reflect the whole spectrum of Kant scholarship. Readings of the deduction start either from the assumption of experience and proceed from there analytically to the necessary conditions of experience (the categories and the principles based on them), or take as their starting point some conception of self-consciousness or self-knowledge, either understood in Cartesian purity (a priori unity of apperception) or in phenomenological embeddedness (empirical self-consciousness), and argue from there to the synthetic conditions for the very possibility of such self-awareness. A key insight shared by many interpreters is the mutual requirement of object-knowledge and self-knowledge in Kant.

In interpretations of Kant's transcendental idealism, a major alternative has opened up between those scholars who see things-in-themselves and appearances as different aspects of one and the same things (*two-aspect view*) and those who regard the two as so many different sets of objects (*two-object view*). On the former view appearances are genuine objects. On the latter view they are representations. While the textual evidence is not conclusive for either view, the two-aspect theory has found many adherents because of its ontological economy and its avoidance of a phenomenalist reduction of things to representations.

The central role of human subjectivity in the deduction of the categories and in the defense of transcendental idealism has led to a renewed interest in Kant's philosophy of mind. Kant's theory of subjectivity is more and more seen as an integral part of his theoretical philosophy. Special areas of interest are the essential role of imagination in perception and experience, the distinction between inner sense and apperception, the relation between subjective or psychological and objective or logical grounds of knowledge, and the functional unity of sensibility and understanding. While no one advocates the derivation of the logical from the psychological in the manner of a reductive psychologism, the exact function of specifically psychological considerations in transcendental philosophy remains controversial. There is a minimal consensus that the self involved in the grounding of experience is distinct from the transcendent, noumenal self of the metaphysics of the soul, so forcefully rejected by Kant in the Transcendental Dialectic of the first *Critique*, and equally to be distinguished from the empirical self known through inner experience. Interpreters typically stress the formal and functional rather than the material and substantial sense of this *third*, transcendental self in Kant.

## OTHER WORKS

Important new work on other parts of Kant's philosophy has occurred in three main areas: his practical philosophy, especially ethics; the *Critique of Judgment*, especially its aesthetics; and his philosophy of science. Scholarship on Kant's ethics has widened beyond the limited concern with the principle of morality (categorical imperative) to include other aspects of Kant's ethics as well as the position of Kant's moral theory within his social philosophy in its entirety and within the wider architectonic of the critical philosophy. A main inspiration of the work on Kant's ethics has been the neo-Kantian political philosophy of John Rawls, who sought to extract from Kant's formal approach to morality procedural guidelines for the ideal construction of the principles of social conduct. Increased attention has been paid to Kant's account of agency, the possible grounding of the categorical imperative in a generic conception of practical rationality, and the key features of Kant's moral psychology—including the theory of motivation, the role of moral judgment, and the function of subjective principles of action (maxims).

The move beyond the confines of Kant's foundational writings in moral philosophy has extended not only to his philosophy of law and theory of moral duties contained in the *Metaphysics of Morals* but also to his work in the phi-

osophy of religion, political philosophy, philosophy of history, and anthropology to be found in a number of his smaller works, often written in a more popular vein. The picture of Kant's practical philosophy that emerges from these reconstructions, revisions, and rediscoveries is that of a highly complex theory that is sensitive to the social dimension of human existence and well being able to respond to the charges and challenges posed by utilitarianism and communitarianism as well as virtue ethics.

In work on the *Critique of Judgment*, the standard emphasis on Kant's theory of aesthetic judgments has been widened considerably in recognition of the role of the third *Critique* as a synthesis of theoretical and practical philosophy in a comprehensive philosophy of human cultural development. A main focus of the scholarship on Kant's philosophy of science has been the *Opus postumum* and its attempts to specify the transition from an a priori theory of material nature to physics proper.

## Bibliography

### WORKS BY KANT

*The Cambridge Edition of the Works of Immanuel Kant*, general editors Paul Guyer and Allen W. Wood. 15 vols. This set is the first comprehensive edition of Kant's published works, literary remains, correspondence, and lecture transcripts in English. The individual volumes of this edition are as follows: *Theoretical Philosophy 1755–1770*, translated and edited by Michael Walford with Ralf Meerbote. Cambridge, U.K.: Cambridge University Press, 1992. *Lectures on Logic*, translated and edited by Michael Young. Cambridge, U.K.: Cambridge University Press, 1992. *Opus postumum*. Translated by Eckart Förster and M. Rosen; edited by Eckart Förster. Cambridge, U.K.: Cambridge University Press, 1993. *Practical Philosophy*, translated and edited by Mary J. Gregor. Cambridge, U.K.: Cambridge University Press, 1996. *Religion and Rational Theology*, translated and edited by Allen W. Wood and George di Giovanni. Cambridge, U.K.: Cambridge University Press, 1996. *Lectures on Ethics*, translated by Peter Heath, edited by Peter Heath and Jerome B. Schneewind. Cambridge, U.K.: Cambridge University Press, 1997. *Lectures on Metaphysics*, translated and edited by Karl Ameriks and Steve Narragon. Cambridge, U.K.: Cambridge University Press, 1997. *Critique of Pure Reason*, translated and edited by Paul Guyer and Allen W. Wood. Cambridge, U.K.: Cambridge University Press, 1998. *Correspondence*, translated and edited by Arnulf Zweig. Cambridge, U.K.: Cambridge University Press, 1999. *Critique of the Power of Judgment*, translated by Paul Guyer and E. Matthews, edited by Paul Guyer. Cambridge, U.K.: Cambridge University Press, 2000. *Theoretical Philosophy after 1781*, translated by Henry E. Allison, M. Friedman, G. Hatfield, and Peter

Heath, edited by Henry E. Allison with Peter Heath. Cambridge, U.K.: Cambridge University Press, 2002. *Notes and Fragments*, edited by Paul Guyer. Cambridge, U.K.: Cambridge University Press, 2005. *Anthropology, History, and Education*, translated and edited by Günter Zöller and Robert Loudon. Cambridge, U.K.: Cambridge University Press, 2006. *Natural Science*, translated and edited by Eric Watkins. Cambridge, U.K.: Cambridge University Press, forthcoming. *Lectures on Anthropology*, translated and edited by Robert Loudon. Cambridge, U.K.: Cambridge University Press, forthcoming.

## KANTIAN ETHICS

Ethical theories may be said to be “Kantian” if they take their inspiration or focus from themes in the ethical theory of Immanuel Kant, while attempting something other than interpretation, development, or defense of Kant’s own ethical theory. This is not a hard and fast distinction: What appears the right way to defend some thesis of Kant’s to one may appear to another to be a complete departure from the crucial components of Kant’s critical ethics. Moreover, some, like scholars Onora O’Neill (1975), Marcia Baron (1996), and Barbara Herman (1993), may see their work as exploring and defending the essential elements of Kant’s moral theory, rather than developing an alternative theory inspired by him, even though they do not accept the metaphysical picture Kant thought crucial to his account. Many defenders of Kant’s own account see the austere picture sometimes drawn of his ethics—as based on a rigoristic and formalistic obligation to *duty*—as mistaken, and argue that Kant’s conception of what people are like as moral agents, and of what morality requires of people, is far richer and more satisfying than is often supposed. Still, it is useful to see Kantian theorists as holding that Kant had some crucial or seminal ethical matters right, while at the same time committing himself to claims or views that are from their perspective unacceptable. Thus, Kantian ethicists may be understood as attempting to rework cherished Kantian insights within the bounds of an overall more acceptable framework.

### METAPHYSICS

For many Kantian theorists, the point of departure from Kant is Kant’s metaphysics and the role his metaphysical commitments play in his ethical theory. Kant struggled for a solution to the problem of how moral agents could be held responsible for their actions in a world governed by natural laws of cause and effect. If every event has a cause, which is itself caused, how could one see human action as anything but determined by the causes antecedent to it? And if human action is caused by natural law, in what sense can individuals see themselves as morally responsible?

Kant’s solution to the problem drew on the metaphysical view developed in his *Critique of Pure Reason*, where he distinguished two worlds, one the world of sense—natural, physical, and empirical—and the other rational or “intelligible.” The empirical world is governed by natural law, and effects do follow causes in ways determined by natural law. However, human beings are not

merely natural but rational, and as members of the rational order are capable of “spontaneity”: of producing effects based on determinations of reason, not causes. Because we have these two-fold natures, people occupy both worlds at once, and their actions are simultaneously subject to natural law and (as rational agents) to moral law.

Many Kantian ethicists find the proposal that people are citizens of some nonnatural world of reason implausible and unattractive. They aim to reconstruct the crucial elements of Kant’s ethical theory without Kant’s reliance on these metaphysical speculations. Most Kantian ethics are intended to develop Kantian ethical ideas while drawing on people’s understanding of themselves as simply members of the natural world.

### UNIVERSALIZABILITY

The strain in Kant’s ethics that has found broadest employment is his idea that a practical principle (or “maxim”) suitable for morally worthy action must be one which can hold universally, or, as Kant puts it, can be willed as a universal law; this is the first formulation of his “Categorical Imperative.” Kant thought that when one acts immorally, one makes an exception of oneself, or makes exceptions for “just this one time,” from laws one would will that everyone obey. Morality is thus best understood as the apprehension of principles that are universalizable in their scope and application.

This element of Kant’s thought has echoes in numerous later thinkers. Marcus Singer (1961), for example, focuses on the general logic of what he calls the “generalization principle”: What is right for one person must be right for anyone in the same or similar circumstances. One accepts the force of the question, “What would happen if everyone did that?” and Singer’s theory is a study in the conditions of its legitimate application. Singer maintains that this principle is presupposed by any genuine moral judgment, and is the key to the moral principles that ground any plausible moral theory. However, Singer departs from Kant both in the metaphysical commitments previously described, and in his departure from considering what one could *will* to be universal, to assessing the desirability of the consequences of a principle with universal application.

Alan Gewirth’s moral theory takes on the principle of generic consistency as its supreme moral principle. Like Kant, Gewirth (1978) begins with the premise that people are agents who act for ends; unlike Kant, Gewirth holds that, as agents, one must see the ends one is acting to realize as good. One sees them as good, however, only in light

of certain properties, or “generic features,” of those ends. For example, one might have the end of getting adequate nutrition in virtue of its natural role in healthy life and agency. But then, Gewirth argues, consistency requires that one sees anything else with those “generic features” as good as well; thus, to be consistent, one must see as good adequate nutrition for anyone. Moreover, people are committed to seeing as good not only their capacity for action but also the freedom and well-being that make it possible, and consistency requires that they see these as good for others as well. They must thus see themselves as having claims against others that they respect their “generic rights”: rights to freedom and well-being. But the principle of universalizability requires that, if people see themselves as having claims against others, they must likewise see others as having the same claims against *them*. Thus, as in Kant, the bare idea of agency, coupled with the rational requirement of universalizability, leads to the fundamental moral principle, in this case the principle of generic consistency, “Act in accord with the generic rights of your recipients as well as of yourself” (Gewirth 1978, p. 135).

For many theorists drawing on elements of Kant’s view (Singer is an example), the Kantian approach is attractive as a way to oppose consequentialism in ethics. However, not all consequentialists agree. R. M. Hare (1981) argues that the focus on universalizability can be taken to ground a form of consequentialism. Hare argues that Kant’s insights into the logical properties of moral terms lead, not to Kant’s own ethical conclusions, but to a form of utilitarianism. This is because people must recognize that moral principles are *prescriptions* of a certain sort, namely universal prescriptions. But such prescriptions are in turn best understood as a sort of *preference*, and when one considers one’s preferences as being constrained by the requirement that they hold universally, one sees that one’s prescriptions must take the familiar consequentialist form of maximizing utility.

## RESPECT FOR PERSONS

The second formulation of Kant’s categorical imperative stipulates that persons are not to treat other persons as means only, but always at the same time as ends. Kant is often thought to have identified something crucial to a proper understanding of morality in this principle, and this way of understanding our obligations of respect for other persons has been widely influential.

Alan Donagan’s work begins with some of the essential elements recognized in the notion of universalizability, but develops them in a direction more congruent with

this feature of Kant’s theory. Donagan (1977) sees Kant as an exemplar of a moral theory based on a common core that reaches back to the Stoics, the Hebrews, and the Christian tradition. This core is based on the thought that morality is addressed to rational creatures as such, in virtue of their rationality, and that its precepts, or moral law, must somehow be accessible to moral agents in virtue of that rationality. In Donagan’s view, what emerges from scrutiny of this common core is the requirement that every human being be treated with the respect due a rational creature. This is closely related to Kant’s second formulation of the categorical imperative, which Donagan finds superior to the “universal law” formulation of that imperative. Thus Donagan is an example of a Kantian theorist who takes Kant’s starting point in a shared capacity for rationality and ends with a focus on respect for human nature.

Others similarly have found this element of Kant’s work central to their own ethical conceptions. Thomas Hill (1991) interprets the metaphysically hoary elements of Kant’s theory as an examination of what it is for a deliberating agent to choose how to act, what ends to pursue, and so on. From this perspective, one’s “autonomy”—one’s capacity to see oneself as capable of more than simply the pursuit of self-interest or satisfaction of preferences—is crucial, as it presupposes that one’s status as a rational agent must be essential in one’s deliberating about how to act.

However, David Gauthier (1996) argues that the focus on respect for persons as valuable in virtue of their status as rational agents can ground a consequentialist approach as well. Gauthier maintains that Kant’s attention to the value of persons as ends-in-themselves is appropriate, but is incapable of justifying the sorts of claims often made against consequentialist accounts, which by their nature require that value be maximized. Rather, Gauthier argues, Kant’s view that rational agents are ends in themselves is itself a view with a form of value at its core, and there is nothing in the balance of Kant’s theory to block the inference that such value ought to be maximized as a matter of moral obligation.

## CONSTRUCTIVISM

Without question the greatest single influence in Kantian ethics has been the work of John Rawls (1971, 1999). Rawls’s best-known work is in political theory, not ethics, and it draws more from Kant’s *method* than from the content of Kant’s views. Rawls took Kant’s singular contribution to moral theory to be the notion that moral truth is not constituted independently of human reasoning and

rationality—independent of individuals in such a way that moral truth can be treated as an object of investigation, as scientific truth is; instead, moral truth is something that instead people constitute or bring into being (“construct”) through the very process of deliberating about it. In Kant’s own theory, this idea is represented in the argument that people understand moral obligation by way of reflection on what principles could be willed as universal law. This approach brings to the foreground the *procedures* by which individuals deliberate about and attempt to determine fundamental moral principles. Rawls’s political theory consists in large part of the characterization of such a procedure to arrive at principles of justice, which, he argues, are best understood not as something individuals discover, but as something they would arrive at on deliberation under certain carefully crafted conditions. The conditions Rawls specifies for this deliberation are also intended to capture important features of Kant’s conception of what people are like as moral and political agents, in particular the distinction between individual persons, deserving of the sort of respect Rawls believes his theory of justice provides.

Rawls’s influence can be seen not only in political theory, but in a resurgence of interest in Kantian foundations for moral and political theorizing generally. Christine Korsgaard (1996) has adapted the constructivist approach in developing her Kantian ethical theory. On her view people recognize that, as reasoning agents, they need reasons to act, and as they assess where such reasons can come from—as they consider possible “sources of normativity”—they realize in the end that they must come from their own rational natures. People take their reasons, Korsgaard argues, from their “identities,” and fundamental to any and all of these identities is their moral identity—their identity as agents acting on reasons. Reasons, Korsgaard argues, are inherently public, in the sense that they must be shareable among agents, so the enterprise of reflecting on how to act itself gives rise to the principles governing one’s conduct.

## KAPLAN, DAVID

(1933–)

An American philosopher and logician, David Benjamin Kaplan was born in Los Angeles in 1933 and has spent his career mainly at the University of California, Los Angeles: first as an undergraduate student (AB in Philosophy, 1956; AB in Mathematics, 1957); then as graduate student (PhD in Philosophy, 1964), where he wrote the last dissertation Rudolf Carnap supervised; later as a faculty member, where he became Hans Reichenbach Professor of Scientific Philosophy in 1994.

Kaplan is best known for his work in formal semantics, particularly on the semantics of demonstratives and other indexicals: expressions such as *this*, *that purple Mercedes convertible*, *I*, *you*, *here*, *now*, and *actually*. In *Demonstratives*, Kaplan developed a theoretical framework in which sentences express propositions relative to contexts. The content of an expression (relative to a context *C*) is what it contributes to the propositions

expressed (relative to  $C$ ) by sentences that contain it. The content of an expression determines an intension: a function from circumstances of evaluation to extensions (truth-values for sentences, individuals for singular terms, sets of individuals for predicates). Circumstances include at least possible worlds and perhaps also times. The character of an expression determines a function from contexts to contents.

In this framework, indexicals have variable contents but stable characters. For example, relative to a context  $c$  whose agent is  $McX$ ,  $I$  has a content  $x$  (which determines a function that maps every circumstance onto  $McX$  himself); whereas, relative to a context  $c^*$  whose agent is Wyman,  $I$  has a different content  $y$  (which determines a function that maps every circumstance onto Wyman himself). But, relative to either context,  $I$  has the same character (which determines a function that maps  $c$  onto  $x$  and  $c^*$  onto  $y$ ). Kaplan proposed that the character of an expression is its linguistic meaning and that it is an expression's character that is responsible for its cognitive value: The difference in cognitive value between "His pants are on fire!" and "My pants are on fire!" for example, lies in the difference between the characters of the indexicals *his* and *my*.

Indexicals are directly referential: For any context  $C$ , the content  $o$  of an indexical relative to  $C$  is the entity that the function determined by  $o$  maps every circumstance onto. For example, relative to  $c$ , whose agent is  $McX$ , the content of  $I$  is  $McX$  himself. Because indexicals are directly referential, a sentence that contains an indexical expresses a singular proposition (relative to a context  $C$ ): a proposition that contains the entity that is the content of that indexical (relative to  $C$ ). For example, relative to  $c$ , whose agent is  $McX$ , "I'm right" expresses a proposition that contains  $McX$  himself. This proposition can be represented as the ordered pair  $\langle McX, \text{the property being right} \rangle$ .

One surprising feature of this framework is that it allows one to distinguish logical truth and necessity. For example, "I am here now" is a logical truth in something like the following sense: Relative to any context  $C$ , it expresses a proposition that is true relative to the circumstance of  $C$  (at least provided that the agent of  $C$  is located at the time and place of  $C$  at the circumstance of  $C$ ). But, at least relative to most contexts, the proposition expressed by "I am here now" is not necessary: It is not true relative to every circumstance (likewise for "I exist" and " $\phi$  if and only if actually  $\phi$ ").

Kaplan's philosophical thought has moved from Fregeanism to Russellianism. In his 1964 dissertation,

*Foundations of Intensional Logic*, Kaplan developed a Carnapian model-theoretic semantics for Alonzo Church's Fregean logic of sense and denotation. In "Quantifying In" (1968–1969), Kaplan developed a Fregean account of belief ascriptions and of belief, one that allows quantification into belief ascriptions (as in "There is an  $x$  such that Ralph believes that  $x$  is a spy") under certain circumstances. By *Dthat* (1978) Kaplan had turned away from his early Fregeanism toward a Russellian view on which "John is suspicious," for example, expresses a singular proposition, one that contains John himself and that can be represented as the ordered pair  $\langle \text{John, the property being suspicious} \rangle$ .

Kaplan went on to become a major proponent of the previously moribund theory of singular propositions. His Russellianism reached its apogee in *Demonstratives* (1989a), where he argued that indexicals are directly referential and, hence, that sentences containing indexicals express singular propositions. Although, in his 1989 *Afterthoughts*, Kaplan admitted to feeling "a resurgence of atavistic Fregeanism," he continued to treat indexicals as directly referential.

After *Demonstratives* and *Afterthoughts*, Kaplan has worked on a number of further topics. In *Words*, he argued that the relation between a word and its occurrences should be thought of as the relation, not between a type and its tokens, but rather between a perduring entity and its temporal parts. He also suggested that it is a word itself that is responsible for its cognitive value: The difference in cognitive value between "Hesperus equals Hesperus" and "Hesperus equals Phosphorus," for example, lies in the difference between the words *Hesperus* and *Phosphorus*. In work on expressives (expressions such as *ouch* and *oops*), Kaplan suggested that one should shift from a semantics that pairs expressions with entities (*meanings*) to a semantics that pairs expressions with rules for their correct use. Kaplan also suggested that characters might best be understood, not as entities, but rather as such rules.

## KAREEV, NIKOLAI IVANOVICH (1850–1931)

Nikolai Ivanovich Kareev, the Russian historian and philosopher, was educated at Moscow University, where he took his doctorate in history (1884). During the late 1870s and early 1880s he spent several years studying abroad. Kareev taught modern European history, first at Warsaw University and then at St. Petersburg University. He became a corresponding member of the St. Petersburg Academy of Sciences in 1910 and an honorary member of the Soviet Academy of Sciences in 1929. His main historical studies were devoted to eighteenth-century France, especially the Revolution of 1789.

Although a moderate in politics, Kareev was deeply influenced by such radical Russian thinkers as Aleksandr Herzen, Dimitrii Pisarev, Pëtr Lavrov, and N. K. Mikhailovskii. Like Lavrov and Mikhailovskii, Kareev was a “semipositivist,” but he was less influenced by either G. W. F. Hegel or Karl Marx than Lavrov had been. His views of history echo Herzen’s “philosophy of chance.” “History,” Kareev declared, “is not a straight line, not a regular design traced out on a mathematical plane, but a living fabric of irregular and sinuous lines, which are intertwined in the most varied and unexpected ways” (*Osnovnye voprosy* [Fundamental problems], Part I, p. 153).

Kareev’s position in ethics, which he called ethical individualism, was even more Kantian than that of Lavrov’s early works. He defended individual autonomy against three dominant anti-individualist tendencies: that which breaks down the self into a series of psychic events (David Hume); that which turns the individual into an expression of the *Zeitgeist* or *Volksggeist* (Hegel); and that which reduces the individual to a product of socioeconomic relations (Marx). From the point of view of the “human dignity and worth of the individual person,” Kareev insisted, “external [sociopolitical] freedom is a necessary condition for the spiritual growth and happi-

ness of all the members of society” (*Mysli*, 2nd ed., 1896, p. 135).

Kareev rejected the “utilitarian attitude toward the person, which treats her as an object,” adding that the “principle of individuality” guarantees the individual’s right “not to be an instrument or means for another” or reduced to the status of an organ of a “social organism” (*ibid.*, p. 138). In attributing absolute value to individuals as such, Kareev said, we take account of both their natural rights and—as Lavrov had stressed—their present potentiality for future moral and intellectual growth. In the name of this absolute value, Kareev condemned not only political assassination and capital punishment but also euthanasia. On this point he came close not only to Immanuel Kant but also to Lev Tolstoy, whose philosophy of history, like those of Hegel and Marx, he had criticized perceptively and in detail.

## KARMA

Karma (Sanskrit, *karman*; literally, “deed,” “action”) is an adjunct in Indian religious thought to the doctrine of Reincarnation. In one form or another, it is part of the beliefs of Buddhism, Jainism, and Hinduism. The actions of a living being are regarded as having a special class of causal effects that determine his future spiritual condition, both in this life and in succeeding ones. These effects are known as the “fruits” of the action. Good deeds lead to progress toward liberation (*mokṣa*, nirvana); bad ones, to regress from this goal. Usually caste status, disease, prosperity, and so forth are thought to be the consequences of actions in previous lives. Thus, karma is an ethically oriented causal law; and although some Hindus regard karma as the work of God, the concept does not necessitate this interpretation, and the award of deserts is as often regarded as an automatic process in nature.

The archaic notion of karma seems to have been that action as such binds men to the world (and thereby to suffering and ignorance); hence, liberation must involve suspension of all activity. Thus, in Jainism, which represents a very ancient strand in Indian religion, even a good action, although inducing an influx of meritorious karma, ties the person to matter. Indeed, karma, as the force determining rebirth, is itself regarded as a subtle form of matter. Also—and hence the emphasis on “non-injury” (*ahiṃsā*)—especially evil effects follow from a person’s destroying life, even microorganisms. Such ideas lay behind the heroically quietistic Jain ideal of suicide by self-starvation. Moreover, the concept of karma in Vedic

literature had the meaning of ritual act, so that combined with the need to refrain from activity there runs through much Indian ascetic thought the notion that even religious acts, although they may bring heavenly rewards, bind men to the cosmos and to rebirth: heaven is part of the cosmos and itself must be transcended.

These ideas presented a number of problems to speculative and religious thinkers: (1) How can liberation ever be achieved if even the effort to be inactive, and inactivity itself, may be forms of binding action? (2) How can the ordinary man, involved in his worldly duties and concerns, have any hope of escaping rebirth? (3) By what mechanism does karma operate on future births? (4) Why, if karma is what keeps empirical life going, does the saint (*jīvanmukta*), who has attained serenity and release in this life, keep on living? (5) How can there be any human initiative or free will if our present state is inexorably determined by past karma?

Various answers to these questions were given, among them the following: (1) The Jains hold that karmic matter can be annihilated by austerities, so that gradually it can be totally removed from an individual. On the other hand, Buddhism transformed the notion of karma by holding that motives, rather than the acts themselves, are what count and that karma needs craving (*taṇhā*) as a necessary condition of its effectiveness. Hence, by removing craving through the purification of one’s motives, one can find release from rebirth. For the Hindu theologian Śankara, the power of karma depends on ignorance, so that the contemplative knowledge that the Self is the sole reality brings liberation from the continuing effects of karma.

(2) On the one hand, the ordinary man can hope to become a recluse, monk, or holy man in a future life. On the other hand, theistic ideas introduced grace as a countervailing means of liberation. Thus, in the *Bhagavad Gītā* it is stressed that a man, in performing his duties without regard to their fruits and in sole reliance upon the Lord, can escape the bonds of karma. Likewise, in Mahāyāna Buddhism the theory of the transfer of merit involves the belief that the otherwise unworthy individual can be given merit by a bodhisattva (Buddha-to-be) out of the latter’s infinite store, acquired through many lives of heroic self-sacrifice on behalf of living beings; thereby the individual qualifies for rebirth in paradise (where the conditions for attaining nirvana are peculiarly favorable). Thus the operation of karma is short-circuited by grace and faith.

(3) It is commonly held that karma is *adṛṣṭa*, an invisible force, so that the need to postulate an observable

mechanism is evaded. However, among some schools the doctrine that the soul is all-pervasive (and not localized) helps to explain the concept of karmic action-at-a-distance. Traditional medical writings (first or second century) affirm that a person's characteristics are not derived solely from his parents (in this, there is an incipient conflict between modern genetics and the theory of karma).

(4) It is generally held that there is a limited continuance of karmic effects, like the running on of a potter's wheel after the potter has stopped turning it—but when the saint's death occurs, there will be no further rebirth for him.

(5) Various positions are adopted concerning the question of free will. The Buddha, for instance, was clearly impressed by the principle that knowledge of causes gives one the opportunity to determine the future, so that a proper understanding of karma and its causality should in no way involve fatalistic conclusions. He attacked Makkhali Gosāla, a contemporary teacher, for holding a fatalistic predestinationism, allied to extreme asceticism (which was in no sense a cause of final release, but merely symptomatic of one's progress). The Jains held that theoretically, in its pure state, the life monad or soul is capable of any kind of effort: Because of this "omnipotence" it never needs to be subservient to karma.

Although some schools argued that, since the effects of karma are morally regulated, one must presuppose a conscious regulator, namely God, atheistic and agnostic proponents of karma theory held that the difficulties of belief in God are as great as, or greater than, those inherent in assuming the automatic operation of karma. Moreover, belief in God generally involves the notion that unworthy people can short-circuit karma through calling on God in faith, and this cuts against the concepts of moral responsibility and self-help.

## KARSAVIN, LEV PLATONOVICH

(1882–1952)

Russian historian-medievalist and religious philosopher Lev Platonovich Karsavin was born in St. Petersburg, the son of a ballet dancer and master, and the brother of the famous ballerina Tamara Karsavina. He graduated from the Department of History of Petersburg University in 1906 and stayed there as a teacher, doing studies in medieval spirituality and culture. Being a disciple of the prominent medievalist Ivan Grews, he soon started to develop his own approach, which can be considered in retrospect as an early prototype of the method of the French Annales school. His first big monograph (1912) was devoted to the early history of the Franciscan Order and the heretical sects of the Waldenses and Cathars. His next monograph, *Foundations of Medieval Spirituality in the Twelfth and Thirteenth Centuries, Mainly in Italy* (1915), is an important theoretical work of a type close to future studies in historical and cultural anthropology. Here Karsavin developed a methodology for historical studies based on the formation of general concepts like "an average religious person," "basic religious fund," and so forth, and tried to perform a reconstruction of the personality of the medieval individual in all its dimensions. The long-forgotten historical work of Karsavin, which includes also *Introduction to History: The Theory of History* (1920) and *Philosophy of History* (1923), was rediscovered in the 1970s and 1980s (chiefly in influential works by Aron Gurevich) and won recognition as a pioneering effort.

During the period of the Russian Revolution (1917–1922) Karsavin's thought shifted gradually to philosophy. This transition was stimulated by his interest in methodological and philosophical problems of history and Christian doctrine. Like a medieval scholastic thinker, he came to general metaphysical problems from reflection on Christian dogmas. In the same period, important changes in his life took place. Karsavin was opposed to the Bolshevik regime, not politically (he even considered the Bolsheviks to be the only force capable of ruling Russia), but ideologically and spiritually. Having a provocative style, he demonstrated his Christian convictions much more than he had before the revolution, lectured in a theological institute, and became the target of a vicious campaign in the official press. In the summer of 1922 he was arrested and then expelled to Germany together with a large group of noncommunist public figures, including leading religious philosophers (Nikolai

Berdyaev, Sergey Bulgakov, Nikolai Lossky, Semen Frank). In exile, he lived in Berlin (1922–1926), then in Clamart, next to Paris (1926–1928), and finally settled in Lithuania, where he was invited to hold the chair of general history at Kaunas University. Between 1925 and 1929 he took an active part in the Eurasian movement, becoming the leading theoretician of its left wing characterized by pro-Soviet views. During the twenties he wrote all his principal philosophical works, creating an original system of religious metaphysics.

Karsavin's system is the last big system of the so-called metaphysics of All-Unity. This philosophical school founded by Vladimir Solov'ev took the central place in Russian religious philosophy and included leading figures of the Russian religious-philosophical renaissance of the twentieth century. By definition, its systems are based on the fundamental concept of All-Unity that represents a specific transrational principle of inner form describing perfect unity of a manifold such that any part of this manifold is identical to the whole of it. Karsavin gives this concept a new treatment, describing All-Unity as a sophisticated hierarchical system, structured vertically (into components or "moments" of higher and lower order, the latter being subsystems of the former) and horizontally (into a variety of moments of the same order). Vertical connections in this structure are described by the notion of *contractio* borrowed from Nicolas of Cusa, while horizontal ones are characterized by means of *conglomeratio et exglomeratio centri* found in Giordano Bruno and meaning that any two moments of the same order are connected not in a direct (i.e., causal) way, but only via the center of the whole system.

Drawing upon ancient doctrines and using their concepts in a constructivist and systematic way close to the theory of systems, this treatment is both archaizing and modernist. In Karsavin's system, the principle of All-Unity is subordinate to another fundamental principle, that of Tri-Unity, modeled on the Holy Trinity as it is presented in Christian dogma. Karsavin follows here the paradigm of dynamic ontology: Like many metaphysical doctrines, from Plotinus to Hegel, he treats being as a process governed by a triadic principle of development, where All-Unity represents the static aspect of Tri-Unity, its "stopping and rest."

Three ontological notions are identical in Karsavin's system: (perfect) Tri-Unity, God, and (perfect) Person. This trilateral identification also serves as the definition of Person. Human being is interpreted as an imperfect person that strives to perfection, that is, to God; all kinds of collective units, social and religious groups, nations,

and classes are also considered as imperfect, embryonic persons and called *symphonic persons*. Karsavin's personalistic turn was new for the metaphysics of All-Unity, which, starting with the Greeks, had traditionally developed in an impersonal symbolist vein. The personalistic trend is further enhanced in Karsavin's description of the world process. The three stages of ontological dynamics are primal unity, disjoining, reunification; the central stage is interpreted as nonbeing or death. In the act of creation God endows with being the reality that he creates, thus depriving himself of being (kenosis) and voluntarily choosing sacrificial death. This voluntary passing of one's own being to somebody, identical to voluntary sacrificial death for somebody, is the definition of (perfect) love—whence it follows that the creature, striving to God, advances to pass, in its turn, its own being to God and thereby ascends to its own sacrificial death out of love.

Thus Karsavin's philosophy presents itself as an ontological drama of death, sacrifice, and love. These principles of his thought turned out to be perfectly realized in the final years of his life. When in 1944 it was clear that the Soviet Union was about to recapture Lithuania, Karsavin refused to leave and move to the West. In 1946 he was dismissed from the university for his deliberately defiant attitude toward Soviet authorities. In 1949 he was arrested and sent to a concentration camp in Abez, near the polar circle. In the gulag he wrote about ten texts of spiritual poetry and metaphysics and until his final days (he died there from tuberculosis) was a spiritual guide and teacher for his fellow prisoners. After the fall of communism, all of Karsavin's principal works were republished in Russia and have been actively studied.

## KATHARSIS

Katharsis is a beneficial transformation of painful emotions through absorbed contemplation of a powerfully moving work of art. The root meaning of "katharsis" in Greek is cleansing. The word can indicate the removal of impurities from, hence the amelioration of, any kind of substance. Before Aristotle, some philosophers had spoken (metaphorically) of psychological katharsis. Aristotle's student Aristoxenus claimed that Pythagoreans "achieved katharsis of the body through medicine, katharsis of the soul through music" (frag. 26). Plato sometimes employs the terminology of "katharsis" for philosophically extricating the soul or intellect from bodily concerns (e.g., *Phaedo* 67c; compare *Sophist* 226d–231b). But Aristotle was the first person to apply the term "katharsis" to the experience of tragedy.

The last clause of Aristotle's definition of tragedy in *Poetics* 6 describes tragedy as "accomplishing through pity and fear the *katharsis* of such emotions." No further reference to katharsis as the effect of tragedy occurs in the *Poetics*. Controversy over the "katharsis" clause remains acute, with no solution commanding great confidence. At issue are questions like the following: Did Aristotle mean occurrent emotions or underlying dispositions? Are pity and fear the only emotions involved? Is emotion the object or only the agency of katharsis? Does the term "katharsis" carry medical and/or religious overtones? Are the minds of tragedy's spectators purged, purified, clarified, or refined?

Our best aid to interpreting tragic katharsis is the account of musical katharsis in Aristotle's *Politics* 8.6–7, where Aristotle posits both pathological and normal cases of the phenomenon. As pity and fear are specifically cited in this context and further elucidation is promised in a discussion of poetry, there is a clear link with the *Poetics*. While *Politics* 8, focusing on educational needs, distin-

guishes various uses of music, it adopts a fundamentally character-centered view of music's capacity to "change the soul" through the passions (1340a4–b19). Though Aristotle regards both tragedy and music as mimetic (representational and expressive) art forms that arouse intense emotional states in their audiences, in his general moral psychology, ethical judgment, while cognitive, is influenced by feeling (*Nicomachean Ethics* 2.2–5, *Rhetoric* 2.1–11). Hence, we should not drive a wedge between the emotional and cognitive implications of katharsis.

Aristotle partially compares the mental effects of musical katharsis to both medical and ritual katharsis, but he nonetheless keeps musical katharsis independent of those spheres. *Politics* 8 encourages a model of tragic katharsis that integrates cognitive, affective, and ethical reactions into the special pleasure of tragedy. Since these reactions stem from emotional engagement with a mimetic plot structure (*Poetics* 14), and since all experience of mimesis is guided by cognitive awareness (*Poetics* 4), Aristotle's larger theory of tragedy supports the view that katharsis operates together with cognition and pleasure. Even so, katharsis should be viewed not as tragic pleasure per se but as a beneficial transformation of painful emotions, through the absorbed contemplation of a powerfully moving artwork, into a key component of a satisfyingly unified experience.

Because katharsis requires an uninhibited flow of emotion, it may bring a sense of "relief" (*Politics* 1342a14) and reduce any excess. But the popular modern association of katharsis with mere draining of blocked emotion oversimplifies Aristotle's perspective. The combined evidence of the *Poetics* and *Politics* suggests that Aristotle addressed Plato's concerns about emotional responses to art (*Republic* 606) by maintaining that such heightened emotion could channel an ethically valuable alignment of feeling and understanding. If so, it is plausible that his concept of katharsis had application to several art forms, perhaps including comedy.

## KAUFMANN, WALTER ARNOLD (1921–1980)

Walter Kaufmann was born in Freiburg, Germany, on July 1, 1921. He emigrated to the United States in 1939, as conditions in Germany became ominous for those of Jewish descent (Kaufmann's father—although not his mother—had converted to Protestantism, with the consequence that Kaufmann had been raised in that faith; but he converted to Judaism in 1933, in an early display of the sensitivity to religious questions that became one of the central features of his intellectual life). He attended Williams College, from which he graduated in 1941, and then went to Harvard, from which he received an MA degree in Philosophy in 1942. After military service in Europe during the Second World War (in capacities that took advantage of his equal facility in German and in English), he returned to Harvard, receiving his PhD in 1947. He joined the Philosophy Department at Princeton University in the fall of that year, which remained his academic base until his untimely death on September 4, 1980, at the age of only 59, from a mysterious illness he apparently contracted while traveling in Egypt and Africa.

Kaufmann played a major role in the introduction of existential philosophy (of Jean-Paul Sartre in particular) and the rehabilitation of G.W.F. Hegel and Friedrich Nietzsche (who had come to be all too closely associated with the Germany of the kaiser and of Adolf Hitler) in the English-speaking world in the decades following the Second World War. As one of the few members of major philosophy departments in those years who had a strong interest in developments in post-Kantian European philosophy, and as a prolific translator as well as interpreter of the writings of some of the most important figures in that tradition, he emerged as its most prominent, visible,

and articulate champion, during the very decades in which the new Britain-based import of analytic philosophy became dominant in the philosophy departments at most major American universities. Much of Kaufmann's career was spent in often heated conflict as an advocate of the continental tradition (as it came to be called) against the newly dominant analytical paradigm that he regarded as a disaster for philosophy, and also as an advocate of those within that tradition (Hegel, Nietzsche, Sartre, and Martin Buber in particular) against the influence and popularity of others within it of whom he had a very low opinion (such as Karl Marx and Martin Heidegger).

Because Kaufmann had a Jewish identity and made no secret of it (even though he also made much of his rejection of Jewish theology), he was ideally positioned to be able to reject the charge of anti-Semitism that had contributed to the widespread hostility to Nietzsche before, during, and after the war years, and to defuse the imputation to Nietzsche of other proto-Nazi sentiments along with it. His association of Nietzsche with Sartrean existentialism was another of his strategies in pursuit of this objective; for, unlike Heidegger, Sartre's anti-Nazi credentials were impeccable, and Sartre himself sought to portray his existentialism as a kind of radical humanism. Kaufmann further presented Nietzsche as a kindred spirit of the heroes of the Enlightenment, and even of Emersonian individualism and later American pragmatism. This interpretation of Nietzsche found a ready reception in a wide and growing audience in the years following the publication of Kaufmann's classic *Nietzsche: Philosopher, Psychologist, Antichrist* in 1950, which remains one of the best general introductions to Nietzsche's thought written for English-speaking readers.

Moreover, while Kaufmann never published another book-length study of Nietzsche, he exerted an even greater influence upon the reception of Nietzsche in the English-speaking world through his much-needed new translations of (and introductions and notes to) most of Nietzsche's major works over a period of two decades, beginning with his phenomenally popular anthology *The Portable Nietzsche* in 1954, culminating with Nietzsche's *The Gay Science* in 1974, and including the controversial collection of selections from Nietzsche's notebooks from the 1880s published after his death under the title *The Will to Power*, thereby giving that volume a prominence and appearance of legitimacy that many feel it does not deserve. And by passing over the various works Nietzsche published between *The Birth of Tragedy* and *Thus Spoke Zarathustra*, Kaufmann influenced what English-

speaking readers ever since have come to regard as Nietzsche's most important works.

Kaufmann simultaneously attempted to renew interest in Hegel, in a manner intended to liberate Hegel from the moribund tradition of interpretation that had flourished in Britain and America under the banner of idealism in the late nineteenth and early twentieth centuries. Kaufmann's Hegel was closer to existentialism than he was to that metaphysical idealism, as he tried to show in his *Hegel: A Reinterpretation* (1966); and his Hegel championed a political philosophy that was a major, but sadly forgotten and neglected, alternative to the options upon which attention was focusing in both analytical and Marxist circles at that time. So Kaufmann first published a study of *Hegel's Political Philosophy* (1970), and then a volume of his own essays in this area reflecting his own mix of Hegelian and Nietzschean elements, *Without Guilt and Justice* (1973). He aspired to be taken seriously as a moral, social, and political philosopher; but the failure of these volumes to attract significant attention led him to turn his efforts in other directions.

Kaufmann had followed his early study of Nietzsche and anthology of Nietzsche's writings with two very popular volumes attempting to do the same thing for existential philosophy—his anthology *Existentialism from Dostoevsky to Sartre* (1956), which was everyone's introduction to existentialism for many years, and his collection of essays *From Shakespeare to Existentialism* (1959), which sought to situate existentialism in intimate if not entirely harmonious relation to an intellectual tradition that included the greatest contributions to Western literature and thought. The relationship between existential and tragic thought, literature, and experience held a particular fascination for him, which he explored in his *Tragedy and Philosophy* (1968).

These interests led Kaufmann to attempt to position himself in relation to traditional forms of philosophical and religious thought, first in his combative early *Critique of Religion and Philosophy* (1958), and then in his impassioned attempt to formulate and articulate his own post-traditional secularly religious credo *The Faith of A Heretic* (1960). His attempts to come to terms with religion continued in two volumes published in 1976, a volume of essays on *Existentialism, Religion, and Death*, and a book intended for a wider audience and marking the beginning of his attempt to integrate philosophy and photography, *Religions in Four Dimensions: Existential and Aesthetic, Historical and Comparative*.

This experiment continued in a trilogy published three years later (1979), under the general title *Man's Lot*.

In this three-volume study of the human condition—*Life at the Limits*, *Time Is an Artist*, and *What Is Man?*—Kaufmann revealed himself as a truly gifted photographer with a powerful ability to employ that gift in the service of his attempt to plumb the heights and depths of human reality. That trilogy was followed by another, *Discovering the Mind* (1980–1981), with which his life abruptly ended, and the third volume of which was published following his death.

In each of these three last volumes Kaufmann considered the contributions of three major figures to this discovery: J.W. Von Goethe, Immanuel Kant, and Hegel; Nietzsche, Heidegger, and Buber; and Sigmund Freud, Alfred Adler and Carl Jung. This, he believed, was the real philosophy of mind; and it was his hope, through these volumes, to enrich philosophical thinking with respect to the mind by connecting it with this tradition—as he had sought to enrich philosophical thinking with respect to the human condition in the previous trilogy, and to enrich moral, social, and political thought by an infusion into them of Hegelian and Nietzschean ways of thinking.

Kaufmann found it at first frustrating and then deeply distressing that he was not taken seriously by the new analytic-philosophical establishment of his day, other than (by some) as Nietzsche's best translator and most appealing reinterpreter. This made him increasingly estranged from and critical of that establishment and philosophical orientation, and may have prompted his involvement in his last years with the EST human potential movement and his willingness to be associated with the Moon Unification Church's International Conference on the Unity of Sciences in the 1970s.

His later work itself was of a character that could hardly have been more at odds with the aims and paradigms of analytic-philosophical inquiry. Yet he considered himself to be true to the real heart and soul of the Socratic philosophical tradition, and to be its advocate and defender in a time in which he felt academic philosophy had lost its way. He welcomed the opportunity to enter the fray of popular debate as a public intellectual who was more than willing to continue Nietzsche's effort to fight the good fight of disillusioned enlightenment that was neither religious, scientific, nor historically optimistic. He thought that philosophy could and should make a difference in human life, and that that difference should be in the direction of an uncompromisingly secular, post-metaphysical, strongly individualistic, but intensely interpersonal, existential humanism. Had he lived to develop and make a case for that vision of authentic humanity, he might well have attained the

recognition in the philosophical community that escaped him.

## KAUTSKY, KARL (1854–1939)

Karl Kautsky was, with the exception of Karl Marx and Friedrich Engels, the leading theorist of orthodox Marxism before World War I. Born in Prague of Czech and German parentage, Kautsky studied at Vienna and showed much interest in social Darwinism and socialism. As an evolutionist and materialist, he found Marx's combination of dialectical materialism and economic determinism irresistible, and he worked with Engels himself during the 1880s. From 1883 to 1917 Kautsky was the editor of *Die neue Zeit*, the official organ of the German Social Democratic Party and the most influential socialist journal of the day. He edited and published the literary remains of Marx after Engels's death. In 1891 Kautsky wrote the famous first, or theoretical, part of the *Erfurter Programm*, the official policy statement of the German

party. This document established that the greatest socialist party in history should be orthodox Marxist.

Kautsky, more than any other theorist of repute, accepted Marx's method and conclusions as he found them. The natural laws of economic development resulted in certain inevitable contradictions in capitalism that must necessarily lead to its destruction and replacement by socialism. This would occur, Marx and Kautsky held, because competition and technical improvements, together with the availability of surplus labor, would lead to the concentration of capital and the progressive immiserization of the proletariat, as well as the polarization of society into a few monopolists opposed by vast masses of starving workers. Recurrent depressions and economic catastrophes would finally destroy capitalism. Such crises would be caused mainly by the inability of the workers to purchase the products of their labor. The united proletariat, trained by its socialist leaders, would see that only social ownership of the means of production could end the contradiction between capitalism's ability to produce wealth and its inability to distribute that wealth through private ownership. Like Marx and Engels, Kautsky held that religion, philosophy, and ethics are reflections of the substructure of class interest and position and that the state is the puppet of the dominant social class.

Kautsky, the "defender of the faith," fought attempts of fellow socialists to make basic alterations in their Marxian heritage. He led the German Social Democratic Party in its struggle against Eduard Bernstein and the revisionists, who believed that the facts of European capitalism no longer supported his orthodox views and that parliamentary action and pragmatic flexibility could bring extensive and permanent reform. Kautsky was able to maintain the preeminence of orthodox Marxism in party theory, although the revisionists increasingly dominated party tactics and action. In the early years of the twentieth century, Kautsky and the orthodox centrists had increasingly to contend with the radical left wing of the party under Rosa Luxemburg and Karl Liebknecht. This group held strictly to Marx's economic teachings but rejected orthodox political tactics in favor of more immediately revolutionary doctrines. They hoped for more radical positions on questions before parliament and for greater encouragement of spontaneous revolutionary and general strike activity. Kautsky did not believe that the contradictions of capitalism or the class consciousness of the workers were advanced enough for such tactics. He did join the Left in parliament on various crucial ques-

tions, notably in its refusal to sanction the continuance of World War I as a war of conquest.

During the Weimar Republic, Kautsky lost his pre-eminent position as the reformists dominated the party and Leninism captured the Left. He was attacked by V. I. Lenin and Leon Trotsky for his castigation of their dictatorial and terroristic methods and their conquest of Georgia, then an independent socialist-controlled state. Forced into exile by the Nazis, Kautsky died in Amsterdam.

## KAVELIN, KONSTANTIN DMITRIEVICH (1818–1885)

Konstantin Dmitrievich Kavelin, the Russian historian and philosopher, was educated at Moscow University, where he was later professor of history. Kavelin also taught at St. Petersburg University and was for a time tutor to the royal family. In addition to numerous histor-

ical works, he wrote essays in psychology, sociology, and ethics. During the 1870s he carried on an active polemic with Vladimir Solov'ëv, defending a positivist (or "semi-positivist") position against Solov'ëv's criticisms. In politics Kavelin was a moderate liberal; in religion he remained devoutly Russian Orthodox.

Kavelin's main work in ethical theory, *Zadachi etiki* (Tasks [or problems] of ethics), appeared in 1844. In it he criticized the then fashionable one-sided "objectivism," which, he charged, blurred the distinction between inner intention and outward behavior, leading to the conclusion that intentions may be "unlawful" or volitions "criminal." From the neo-Kantian viewpoint that Kavelin adopted in this book, such a conclusion is absurd. Intentions and volitions, he insisted, are to be judged only "by their relationship to consciousness, to the understanding and inner conviction of the person in whom they occur" (*Sobranie sochinenii* [Collected works], Vol. III, col. 907).

When utilitarians equate virtue with utility and vice with social harm they are taking an "outsider's" view of moral experience, the view of a spectator rather than that of a moral agent. In fact, moral virtue may or may not be useful; this depends on the particular social system involved, and the latter is a nonmoral factor. Hence, social utility cannot provide a sound criterion of morality.

It is human individuality as a unique locus of value, Kavelin asserted, which provides such a criterion. However, this assertion raised serious problems for Kavelin's "scientific ethics," since, as he admitted, concrete individuality systematically eludes the abstract generalities of science. In the end, the "scientific ethics" that Kavelin had been laboring to construct coincided with Christian ethics—the "last word in ethical wisdom" and "an incontrovertible truth of individual spiritual life" (*Sobranie sochinenii* [Collected works], Vol. III, Cols. 940–941).

Kavelin's attempt to provide a scientific foundation for ethics, like the attempts of other nineteenth-century thinkers, must be judged a failure. However, Kavelin eloquently restated ideas derived from Vissarion Belinskii, Aleksandr Herzen, and the Russian Populists concerning the individual person and his sense of freedom and the role of convictions in morality. His was a genuine, if modest, philosophical contribution.

## KELSEN, HANS

(1881–1973)

Born in Prague on October 11, 1881, Hans Kelsen grew up in Vienna. He studied law at the University of Vienna and completed, in 1911, the *Habilitation* (major dissertation required for the *venia legendi* or state license to hold university lectures). After military service in World War I, he worked up a number of drafts of what became the Austrian Federal Constitution of October 1920. Here Kelsen's most distinctive contribution was centralized constitutional review, an entirely new institutional practice. During the 1920s, Kelsen served as professor of law at the University of Vienna and also as Constitutional Court judge. Ousted from the latter position in 1930 by Austria's right-of-center Christian-Social Party, Kelsen took up a professorship in Cologne. Ousted from this position in the spring of 1933, on the basis of the notorious Nazi statute for the "Restoration of the Professional Civil Service" (authorizing the dismissal of those seen as politically unreliable and also those of Jewish ancestry), Kelsen spent the period from 1933 to 1940 in Geneva. He left in May 1940 for the United States, where he eventually secured a position at the University of California at Berkeley. He died in Berkeley on April 19, 1973.

Kelsen's juridico-philosophical work breaks down into three phases, although there is no bright line between the first two. Kelsen's first phase, critical constructivism, runs from 1911 to approximately 1920. His primary concern is to show that naturalism in legal science is mistaken, and he goes on to construct the basic concepts of the law in nonnaturalistic/non-naturalistic terms. Kelsen's second phase, his classical or Neoneo-Kantian period, picks up at the end of the first phase and runs up to 1960. It is marked by two major developments.

The first of these is Kelsen's attempt to provide a foundation for the concepts he constructed in the first phase. His "purity postulate" precludes any appeal either to natural law or moral theory on the one hand, or to empirical data on the other. What remains? Kelsen answers with a transcendental argument, proceeding in standard Neoneo-Kantian fashion from the *Faktum der Wissenschaft* (here, the fact of legal science) to the necessity of the basic norm *qua* normative category. Without the normative category, legal science would not be possible, but since legal science is given, it must be the case that the normative category is presupposed.

A rather different development in the early years of the second phase is represented by Kelsen's adoption of the *Stufenbaulehre* (doctrine of hierarchical structure) from his gifted Vienna colleague, Adolf Julius Merkl. This doctrine calls for ever-greater concretization as the law moves from the general norms of the constitution, at the apex of the hierarchy, to individual legal acts of law—implementation at its base. Accommodating norms that represent every species of law (constitutional rule, statutory provision, administrative regulation, official's legal act), the doctrine gives the lie to later nineteenth-century *Gesetzespositivismus* (statutory positivism), which held that the statute alone was characteristic of the modern legal system. In a juridico-philosophical vein, the doctrine of hierarchical structure marks the introduction, into Kelsen's theory, of empowering norms, which, as he argues at a later point, represent the most fundamental normative modality.

In his third and last phase, beginning in 1960, Kelsen throws overboard the Neoneo-Kantian edifice of the classical phase and defends a will theory of law—a remarkable development in the case of a philosopher who, for literally half a century, had criticized the will theory as well-nigh wrong-headed. Kelsen's skepticism in this last phase is reflected, for example, in his rejection of any role for logic in the law.

Kelsen's significance stems not least of all from his work on the philosophically difficult concept of normativity. A "strong normativity thesis," defended as an interpretation of Kelsen by Joseph Raz, speaks to the classical question in legal philosophy, namely, whether—and, if so, how—the obligation to obey the law is to be justified. A "weak normativity thesis," which reflects Kelsen's abiding interest in preserving the autonomy of the law and, by the same token, the "purity" of legal science, looks to normativity in the name of noncausal change as Kelsen's juridico-philosophical alternative to naturalism.

## KEPLER, JOHANNES

(1571–1630)

Johannes Kepler, the founder of modern astronomy, was born in Weil der Stadt, near Stuttgart. During his life he was a student of theology, teacher of mathematics and astronomy, assistant to Tycho Brahe, imperial mathematicus to the emperors Rudolf II and Matthias, and astrologer to the duke of Wallenstein. His principal scientific discoveries were the three planetary laws named after him, the principle of continuity in geometry, and the Keplerian telescope. He was also responsible for decisive advances in the theory of optics and in work that led to the development of the infinitesimal calculus, and incidentally he coined a number of terms whose paternity has been forgotten, including *satellite* (for the moons of

Jupiter), *dioptrics*, *focus* (of a conic section), and *camera obscura*.

### SIGNIFICANCE OF KEPLER'S LAWS

Kepler's three laws of planetary motion postulate that the planets travel in elliptical orbits, one focus of each ellipse being occupied by the sun; that the radius vector connecting sun and planet sweeps over equal areas in equal times; and that the squares of the periods of revolution of any two planets are in the same ratio as the cubes of their mean distances from the sun.

The promulgation of the three laws was in several respects a turning point in the history of thought. They were the first "laws of nature" in the modern sense: precise, verifiable statements, expressed in mathematical terms, about universal relations governing particular phenomena. They put an end to the Aristotelian dogma of uniform motion in perfect circles, which had bedeviled cosmology for two millennia, and substituted for the Ptolemaic universe—a fictitious clockwork of wheels turning on wheels—a vision of material bodies not unlike Earth freely floating in space, moved by physical forces acting on them. Kepler's laws severed the ties between astronomy and theology and replaced the moving spirits of medieval cosmology by physical causation.

What has come to be called the Copernican revolution was in fact mainly the work of Kepler and Galileo Galilei. Kepler's laws and Galileo's studies on the motion of projectiles were the basic ingredients of the Newtonian synthesis. Nicolas Copernicus's *De Revolutionibus* was published in 1543, nearly thirty years before Kepler was born. Its first edition of a thousand copies never sold out, and it had altogether four reprintings in 400 years. By way of comparison, Christopher Clavius's textbook *The Treatise on the Sphere* had nineteen reprintings within fifty years; Copernicus's book had one. This curiosity is mentioned because it illustrates the fact that the Copernican theory attracted very little attention on the continent of Europe for more than fifty years—that is, for the next two generations. *De Revolutionibus* was an unreadable book describing an unworkable system. It revived the Pythagorean idea of a heliocentric universe, first proposed by Aristarchus of Samos in the third century BCE, but it adhered to the dogma of circular motion. As a result, Copernicus was forced to let the planets run on no less than forty-eight epicycles and eccentrics. He was in fact, as Kepler remarked, "interpreting Ptolemy rather than nature."

Kepler was the first astronomer to raise his voice in public in favor of the Copernican system. His *Mysterium*

*Cosmographicum*, published in 1597, fifty-four years after Copernicus's death, initiated the controversy; Galileo only entered the scene fifteen years later. At that time Kepler—aged twenty-six—knew little of astronomy. He had started as a theologian, but a chance opportunity made him accept the post of teacher of mathematics and astronomy at the provincial school of Gratz in Styria. Three years later, however, he became assistant to Tycho Brahe, whose observational data, of a hitherto unparalleled richness and precision, provided the empirical foundation for Kepler's efforts to determine the orbit of Mars. It took Kepler eight years of nerve-racking labor to succeed. The result was his magnum opus, published in 1609, which contains the first and second laws (the third came nine years later). It bears a provocative title:

A NEW ASTRONOMY *Based on Causation*  
 OR A PHYSICS OF THE SKY  
*derived from Investigations of the*  
 MOTIONS OF THE STAR MARS  
*Founded on Observations of*  
 THE NOBLE TYCHO BRAHE.

The title is indeed symbolic of the work's revolutionary intent and achievement. Astronomy before Kepler had been a purely descriptive geometry of the skies, divorced from physical reality. Since the observed motions of the planets did not conform to the demands of circularity and uniformity, an increasing number of auxiliary wheels had to be added to the fictitious clockwork to save the phenomena. These wheels were thought to be somehow connected with the eight crystal spheres of medieval cosmology, which were kept in motion by a hierarchy of angels, but any pretense to regard them as a physically workable model had to be abandoned. The situation was summed up in a famous remark by Alfonso X of Castile, called the Wise, when he was initiated into the Ptolemaic system: "If the Lord Almighty had consulted me before embarking on the Creation, I should have recommended something simpler."

Copernicus upset the cosmic hierarchy by placing the sun in its center, but his universe was still cluttered (in John Milton's words) "with centric and eccentric scribbled o'er, Cycle and epicycle, orb in orb." It was Kepler who, by banishing epicycles and eccentrics "to the lumber-room" (as he wrote), finally demolished the very scaffolding, as it were, on which the medieval universe rested and replaced its hierarchy of spirit forces with the interplay of physical forces. The tortuous way in which he achieved this may serve as a cautionary tale to scientists and philosophers and represents a significant episode in the history of thought.

## MYSTICISM AND EMPIRICISM

In Kepler all the contradictions of his age seem to have become incarnate—the age of transition from the medieval to the "new philosophy," as the scientific revolution was called by its founders. One half of his divided personality belonged to the past; he was a mystic, given to theological speculation, astrology, and number lore. However, he was also an empiricist with a scrupulous respect for observational data, who unhesitatingly threw out his earlier theory of planetary motions, the product of five years of dogged labor, because certain observed positions of Mars deviated from those that the theory demanded by a paltry eight-minute arc. He later wrote that Ptolemy and Copernicus had been able to shrug away such minor blemishes in their theories because their observations were accurate only within a margin of ten minutes, anyway, but those who, "by divine kindness," were in possession of the accurate observations of Brahe could no longer do so. "If I had believed that we could ignore those eight minutes," he wrote in the *Astronomia Nova* (II, Ch. 19), "I would have patched up my hypothesis accordingly. But since it was not permissible to ignore them, those eight minutes point the road to a complete reformation of astronomy."

This newfound respect for hard, obstinate facts was to transform what used to be called "natural philosophy" into the "exact" (or "experimental") sciences and to determine, to a large extent, the climate of European thought during the next three centuries. It provided Kepler with the necessary discipline and put a restraint on his exuberant fantasy, but the primary motivation of his researches was mysticism of a Pythagorean brand. Throughout his life he was obsessed by certain mystic convictions, each of which had the power of an *idée fixe*. The first was the belief that the solar system was patterned on the perfect, or "Pythagorean," solids (Saturn's orbit circumscribed a cube into which was inscribed the orbit of Jupiter; into this was inscribed the tetrahedron that circumscribed the orbit of Mars; and so on down to the octahedron inscribed into the orbit of Mercury). The second was the equally Pythagorean belief that the planetary motions were governed by musical harmonies (the book containing the third law is called *Harmonice Mundi*). Fortunately, both lent themselves to mathematical juggling almost ad lib, until they fitted the data. Far from interfering with his reasoning powers, these irrational obsessions were harnessed to his rational pursuits and provided the drive for his tireless labors. From a subjective point of view, Kepler's fundamental discoveries were in fact merely by-products of his chimerical quest. Toward the end of his

life he proudly mentioned in retrospect some of his minor achievements, but there is no mention whatsoever of his epoch-making first and second laws.

### EMERGENCE OF THE CONCEPT OF FORCE

The apparent paradox of a mystically inspired prejudice acting as a spur to scientific achievement is most clearly exemplified in the circumstances that led Kepler to introduce into astronomy the concept of physical forces. As has already been stated, he started his career as a student of theology (at the Lutheran University of Tübingen). The reason the concept of a heliocentric universe attracted the young theologian was later stated by him repeatedly. Thus, in the “Preface to the Reader” of his *Mysterium Cosmographicum* he explained that he had often defended the opinions of Copernicus in the discussions of the candidates at the seminary and had also written “a careful disputation on the first motion which consists in the rotation of the earth around the sun *for physical, or if you prefer, metaphysical reasons.*” (The last phrase is emphasized because it is repeated verbatim in various passages in Kepler’s works.)

He then proceeded to explain the nature of these “metaphysical reasons.” They were originally based on a supposed analogy between the stationary sun, the stars, and interstellar space, on the one hand, and God the Father, the Son, and the Holy Ghost, on the other. In his first book the young Kepler promised the reader to pursue this analogy in his future cosmographical work; twenty-five years later, when he was over fifty, he reaffirmed his belief in it. “It is by no means permissible to treat this analogy as an empty comparison; it must be considered by its Platonic form and archetypal quality as one of the primary causes” (*Mysterium Cosmographicum*, note to 2nd ed.).

He stuck to this belief to the end of his life, as he stuck to the Pythagorean solids and the harmony of the spheres. But gradually his cherished analogy underwent a significant change. The fixed stars were replaced by the moving stars—the planets. The sun in the center of the planets, “himself at rest and yet the source of motion,” continued to represent God the Father, and “even as the Father creates through the Holy Ghost” so the sun “distributes his motive force through a medium which contains the moving bodies” (letter to Maestlin, March 10, 1595).

Thus, the Holy Ghost no longer merely fills the space between the motionless sun and the fixed stars. It has become an active agent, a *vis motrix* that drives the plan-

ets. Nobody before had suspected the existence of such a force emanating from the sun. Astronomy had been concerned not with the causes of the heavenly motions but with their description. The passages just quoted are the first intimation of the forthcoming synthesis of cosmology and physics. Once he conceived the idea, derived from his analogy, that the sun was the source of the power that makes the planets go round, Kepler hit upon a question no one else had asked before him: Why do the planets closer to the sun go round faster than those farther away? His first answer to it, in the *Mysterium Cosmographicum*, was that there exists only one “moving soul” in the center of all the orbits—that is, the sun—which drives the planets “the more vigorously” the closer they are, but by the time it reaches the outer planets the force is quasi exhausted “because of the long distance and the weakening of the force which it entails.”

Twenty-five years later, in the notes to the second edition, he commented that if we substitute for the word *soul* the word *force*, “then we get just the principle which underlies my physics of the skies.” He continued to explain that he had once firmly believed the motive force was a soul; yet as he reflected that the force diminishes in proportion to distance, just as light diminishes in proportion to distance, he came to the conclusion “that this force must be something substantial—‘substantial’ not in the literal sense but . . . in the same manner as we say that light is something substantial, meaning by this an unsubstantial entity emanating from a substantial body.”

The twenty-five years that separate these two quotations mark the transition from *anima motrix* to *vis motrix*, from a universe animated by purposeful intelligences to one moved by inanimate, “blind” forces devoid of purpose. For the rest of his life Kepler struggled with this new concept emerging from the womb of animism (its very name, *virtus*, or *vis*, betrays its origin) without ever coming to terms with it. At first he was not aware of the difficulties inherent in it. In a letter to a friend, which he wrote when the *Astronomia Nova* was nearing completion, he outlined his program:

My aim is to show that the heavenly machine is not a kind of divine, live being, but a kind of clockwork (and he who believes that a clock has a soul, attributes the maker’s glory to the work), insofar as nearly all the manifold motions are caused by a most simple, magnetic, and material force, just as all motions of the clock are caused by a simple weight. And I also show how these physical causes are to be given numerical and

geometrical expression. (Letter to Herwart, February 10, 1605)

Kepler had defined the essence of the scientific revolution. But it turned out to be easier to talk about a “most simple, magnetic, material force” than to form a concrete idea of its working. Kepler’s efforts to visualize the nature of the “moving force” emanating from the sun are not only of exceptional interest from the historian’s point of view; they also illuminate the philosophical difficulties that were inherent in the concept of “force” from its very beginning. Since no English translation of the *Astronomia Nova* was published by the time this article was written, a few quotations may be found in order. First, Kepler compared the “moving force” of the sun with the light emitted by it:

Though the light of the sun cannot itself be the moving force ... it may perhaps represent a kind of vehicle, or tool, that the moving force uses. But the following considerations seem to contradict this. First, the light is arrested in regions that lie in shade. If, then, the moving force were to use light as a vehicle, darkness would bring the planets to a standstill. ...

This kind of force, just like the kind of force that is light, ... can be regarded not as something that expands into the space between its source and the movable body but as something that the movable body receives out of the space it occupies. ... It is propagated through the universe ... but it is nowhere received except where there is a movable body, such as a planet. The answer to this is: although the moving force has no substance, it is aimed at substance, i.e., at the planet-body to be moved. ...

Who, I ask, will pretend that light has substance? Yet nevertheless it acts and is acted upon in space, it is refracted and reflected, and it has quality, so that it may be dense or sparse and can be regarded as a plane where it is received by something capable of being lit up. For, as I said in my *Optics*, the same thing applies to light as to our moving force: it has no present existence in the space between the source and the object it lights up, although it has passed through that space in the past; it “is” not, it “was,” so to speak. (*Astronomia Nova*, III, Ch. 33)

Thus, Kepler’s gropings brought him closer to the modern concept of the field than to the Newtonian concept of force, and the modern scientist grappling with the paradoxes of quantum theory will find here an echo of

his own perplexities. This may be the reason Kepler, having hit on the concept of universal gravity, subsequently discarded it—as Galileo and René Descartes were to discard it.

## GRAVITY AND ANIMISM

The most precise pre-Newtonian formulations of gravity are to be found in the preface to the *Astronomia Nova*. Kepler started by refuting the Aristotelian doctrine according to which all “earthy” matter is heavy because it is its nature to strive toward the center of the world—that is, Earth. But all “fiery” matter strives by its nature toward the periphery of the universe and is therefore light. Kepler explained that there is no such thing as lightness, but, rather, the

matter that is less dense, either by nature or through heat, is relatively lighter ... and therefore less attracted [to the earth] than heavier matter. ... Supposing the earth *were* in the center of the world, heavy bodies would be attracted to it, not because it is in the center, but because it is a material body. It follows that regardless of where we place the earth, heavenly bodies will always seek it. ...

Gravity is the mutual bodily tendency between cognate [i.e., material] bodies toward unity or contact (of which kind the magnetic force also is), so that the earth draws a stone much more than the stone draws the earth. ...

If the earth and the moon were not kept in their respective orbits by a spiritual or some equivalent force, the earth would ascend toward the moon 1/54 of the distance, and the moon would descend the remaining 53 parts of the interval, and thus they would unite. But this calculation presupposes that both bodies are of the same density.

If the earth ceased to attract the waters of the sea, the seas would rise and flow into the moon. ...

If the attractive force of the moon reaches down to the earth, it follows that the attractive force of the earth, all the more, extends to the moon and even farther. ...

If two stones were placed anywhere in space near to each other, and outside the reach of force of a third cognate body, then they would come together, after the manner of magnetic bodies, at an intermediate point, each approaching the other in proportion to the other’s mass.

In the same passage is to be found the first approximation to a correct theory of the tides, which Kepler explained as “a motion of the waters toward the regions where the moon stands in the zenith.” In a work written at the same time—“*Somnium—A Dream of the Moon*” (an early exercise in science fiction)—he furthermore postulated that the sun’s attraction, too, influences the tides—that is, that the gravitational force of the sun reaches as far as Earth.

But here we are faced with another paradox. In the preface to the *Astronomia Nova*, Kepler, as we have seen, had grasped the essence of gravity and even the idea that its force is proportionate to its mass; yet in the text of *Somnium*, and all subsequent works, he seems to have completely forgotten it. The force that emanates from the sun in the Keplerian universe is not a force of attraction but a tangential force, a kind of vortex or “raging current which tears all the planets, and perhaps all the celestial ether, from West to East.”

To the question of what made Kepler drop gravity no answer is found anywhere in his profuse writings. Everything points to some unconscious psychological blockage, and we may gather hints about its nature in the writings of the other pioneers of the scientific revolution. Kepler’s suggestion that the tides were caused by the moon’s attraction Galileo indignantly rejected as an “occult fancy” (*Dialogue concerning the Two Chief World Systems*). Descartes was equally repelled by the idea of a nonmechanical force acting at a distance and, like Kepler, substituted for it vortices in the ether. As for Isaac Newton, his attitude is summed up in his famous third letter to Richard Bentley, in which he said it is inconceivable that “inanimate brute matter” should, without some mediating material substance, act upon other bodies.

That gravity should be innate, inherent, and essential to matter, so that one body may act upon another, at a distance through a vacuum, without the mediation of anything else, by and through which their action and force may be conveyed from one to another, is to me so great an absurdity, that I believe no man who has in philosophical matters a competent faculty of thinking, can ever fall into it.

Kepler, Galileo, and Descartes did not fall into the philosophical abyss; their thinking was much too “modern”—that is, mechanistic—for that. The notion of a “force” that acts without an intermediary agent and pulls at immense stellar objects with ubiquitous ghost fingers appeared to them mystical and unscientific, a lapse into that Aristotelian animism from which they had just bro-

ken loose. Universal gravity, *gravitatio mundi*, smacked of the *anima mundi* of the ancients. Newton overcame the obstacle and made the concept of gravity respectable by invoking a ubiquitous ether, whose attributes were equally paradoxical, and by refusing to speculate on the manner in which gravity worked (his *hypothesis non fingo* refers to this problem, and to this problem only, though it is often quoted out of context). But above all, he provided a precise mathematical formula for the mysterious agency to which gravity referred. That formula Newton deduced from the laws of Kepler, who had intuitively glimpsed universal gravity and shied away from it. In such crooked ways does the tree of science grow.

## SYNTHESIS OF ASTRONOMY AND PHYSICS

In the Aristotelian cosmos, physical forces operated only among the four elements in the sublunary sphere; the motions of the celestial bodies, made of a fifth element, were due to spiritual agencies and governed by the demands of geometrical perfection. Kepler and Galileo broke down this dualism by postulating that physical causality permeates the entire universe. Kepler’s “physics of the sky” we know to have been all wrong. He had no notion of inertial momentum, and he had dropped gravity. In Kepler’s universe the sun exerted a tangential force (diminishing in direct ratio with increasing distance), which the “lazy” planets resisted, and the eccentricity of the orbits was accounted for by magnetic forces. (Since the planets’ magnetic poles always pointed in the same direction, they would be drawn closer to the sun in the aphelion and repelled in the perihelion.)

But though the model was wrong in every detail, his basic assumption, that there were several antagonistic forces acting on the planets, guided him in the right direction. A single force, as previously assumed—the Prime Mover and the allied hierarchy of angels—would never produce elliptical orbits and periodic changes of velocity. These could only be the result of some tug of war going on in the sky, and this dynamic concept, supported by a series of wild ad hoc hypotheses, led him in the end, after countless detours, to his three laws.

Kepler’s determination of the orbit of Mars became the unifying link between two hitherto separate universes of discourse, celestial geometry and earthly physics. His was the first serious attempt to explain the mechanism of the solar system in terms of physical forces. Once the example was set, astronomy and physics could never again be divorced.

## KEYNES, JOHN MAYNARD (1883–1946)

The English economist John Maynard Keynes, the son of a distinguished Cambridge logician and economist, was one of the most brilliant and influential men of the twentieth century. His role as the architect and chief negotiator of Britain’s external economic policies in two world wars was only one side of his public life. During his own lifetime, his economic views, contained primarily in two great works, *A Treatise on Money* (London, 1930) and *The General Theory of Employment, Interest and Money* (London, 1936), revolutionized the economic practice, and to a lesser extent, the economic theory, of Western governments.

Keynes wrote only one philosophical work, *A Treatise on Probability* (London, 1921), but it is a philosophical classic. The following account of the book’s leading ideas adheres to its own main divisions.

### PHILOSOPHY OF PROBABILITY

Keynes’s philosophy of probability is contained chiefly in Parts I and II. For Keynes, only a proposition can be probable or improbable. A proposition has probability only in relation to some other proposition(s) taken as premise(s). Hence a proposition may have different probabilities on different premises. Nevertheless, the probability that  $p$  does have, given  $q$  (which Keynes writes as  $p/q$ , is perfectly objective. Some probabilities are known to us indirectly—for example, as a result of applying the theorems of the probability calculus; but first, of course, some probabilities must be known directly. Where a probability is known to us directly, it is known to us in the way that the validity of a syllogistic argument is known, whatever that way is. The probability relation is not an empirical one. If it is true that  $p/q > r/s$ , or that  $p/q > 1/3$ , or that  $r/s = 1/2$ , then it is true a priori, and not in virtue of any matter of fact. In particular, the truth of such statements is independent of the factual truth of  $p$ ,  $q$ ,  $r$ , and  $s$ . Finally,  $p/q = 0$  if  $p$  is inconsistent with  $q$ , and  $p/q = 1$  if  $q$  entails  $p$ .

Keynes's fundamental thesis, of which the above statements are developments, is that there are inferences in which the premises do not entail the conclusion but are nevertheless, just by themselves, objectively more or less good reason for believing it. This thesis seems to require the existence of different degrees of implication. Such degrees are Keynes's probabilities. Thus, for Keynes the study of probability coincides exactly with the study of inference, demonstrative and nondemonstrative. He developed, though somewhat obscurely, a general theory of inference in Chapter X. However, from the axioms and definitions from which he derived the accepted theorems of the probability calculus, he also derived many theorems of demonstrative inference, for example, "if  $a/h = 0$  then  $ab/h = 0$ ."

It would be hard to exaggerate the importance of Keynes's fundamental thesis. Classical probability theory of the eighteenth and nineteenth centuries must have presupposed some such thesis. Recent theory on degrees of confirmation presupposes it. To Keynes, as to Pierre Simon de Laplace and Rudolf Carnap, this thesis appeared to be necessary as a means of avoiding skepticism about induction. But David Hume would presumably have rejected it outright, and it is by no means free from difficulty.

There are two negative theses that distinguish Keynes's philosophy of probability from most earlier or later formulations. One is that probabilities simply do not have a numerical value, except in certain exceptional circumstances, and never in normal inductive contexts. The other is that there are noncomparable probabilities, that is, probabilities that are neither equal to nor greater nor less than one another. For obvious reasons, these theses have contributed to the neglect of Keynes by statistical writers.

## INDUCTION

In Part III, Keynes discussed induction. The most important arguments of those that are rational but not conclusive belong to the class of inductions whose conclusions are universal generalizations and whose premises are about instances of the generalization.

Keynes, like John Stuart Mill, regarded all scientific induction as essentially eliminative induction. His account of the circumstances in which we regard an inductive argument as strong is, in essentials (although not otherwise), a development in detail of Mill's method of agreement.

The mere number of confirmations of a hypothesis in itself is of no evidential weight. The important thing is the variety of the instances, in respects other than those that constitute the instances' confirming ones. We regard inductions as being of greatest weight when the evidence approaches the ideal case in which the confirming instances are known to be not all alike in every respect. Various ways in which our evidence can fall short of this ideal are discussed in Chapter XIX. Keynes thought that the extent to which the evidence, by its variety, eliminates alternative hypotheses is the only important factor—not only when our hypothesis is empirical, but when it is, for instance, mathematical or metaphysical.

Keynes very clearly distinguished between the task of analyzing those inductive arguments that we regard as strong and the task of justifying the fact that we regard them as strong.

The latter task, he appears to have assumed, requires a proof of the proposition that relative to instantial evidence, the probability of a universal hypothesis can approach certainty as a limit. It will do so, he purported to prove, if (and one must assume only if) the probability of the instantial evidence supposing the hypothesis to be false can be made small in comparison with the probability of the hypothesis prior to the instantial evidence (its "a priori" probability). To reduce the former probability is the object of "varying the circumstances." The required disparity between the two probabilities will exist, Keynes argued, if (and one must assume only if), *inter alia*, the hypothesis has finite a priori probability. This requires that it be a member of a finite disjunction of exhaustive alternatives.

When the universal hypothesis is an empirical one, this amounts to the assumption that there exists in nature the materials for only a finite number of generalizations linking empirical properties. In other words, the number of the logically independent properties of empirical objects, which a priori might have been constantly conjoined, is finite. This is the famous principle of limited independent variety (Chapter XX). Hence, the fact that the probability of any empirical universal generalization should approach certainty as a limit requires the assumption of this principle. Or rather, Keynes thought, all that is required for this principle is finite a priori probability, since experience can and does noncircularly support the principle, provided it does have this initial probability.

It does so, Keynes appears to have argued, because we have a direct apprehension of the truth of the principle, just as, he thought, we have an apprehension (not independent of experience, yet not inductively inferred) of

the truth of the statement, “Color cannot exist without extension.”

### STATISTICAL INFERENCE

The main subject of Part V is those inductive inferences whose premises include a statement of the frequency of a property *B* in an observed series of *A*'s, and whose conclusions concern *B*'s frequency in the population of *A*'s as a whole, or in a further series of *A*'s, or the probability of the next *A* being a *B*.

The theory of statistical inference had been dominated by two methods of making such inferences, both due to Laplace. One is the “rule of succession,” according to which the probability of the next *A* being *B* is

$$\frac{m + 1}{m + n + 2}$$

if *m* out of *m + n* observed *A*'s have been *B*. The other is the “inversion” of the great-numbers theorem of Bernoulli. This theorem permits us—under an important restriction—to infer what frequency of *B* is most probable among observed *A*'s, given its frequency among *A*'s as a whole. Laplace purported to supply a theorem that would guide our inferences in the reverse, inductive direction, that is, from observed *A*'s to *A*'s as a whole.

Keynes regarded both methods as “mathematical charlatanry.” His many criticisms of them cannot be weighed here. Apart from these criticisms, however, he considered it absurd to imagine that we could have exact measures of the probability of statistical conclusions. Statistical induction is subject to all the difficulties that beset inductions with universal conclusions, and to others beside. Moreover, the only evidence taken into account by all methods like Laplace's is numerical. The vital requirement of variety in the instances is neglected. In statistical contexts, the variety of the positive “instances” takes the form of the stability of the observed frequency when the observed series is considered as divided into subseries according to many different principles of division.

Keynes did think that, under a number of extremely stringent conditions, an inversion of Bernoulli's theorem is legitimate. But even to license these inductive inferences, as Keynes interpreted them, the principle of limited independent variety is required.

### Bibliography

Keynes's only philosophical work is *A Treatise on Probability* (London: Macmillan, 1921). On Keynes's life, see R. F. Harrod, *The Life of John Maynard Keynes* (London: Macmillan, 1951).

Valuable critical material on Keynes's theories of probability and induction may be found in the following: Jean Nicod, *Foundations of Geometry and Induction* (London: Kegan Paul Trench and Trubner, 1930); F. P. Ramsey, *Foundations of Mathematics* (London: Kegan Paul Trench and Trubner, 1931); G. H. von Wright, *The Logical Problem of Induction* (Helsingfors, 1941); G. H. von Wright, *A Treatise on Induction and Probability* (London: Routledge and Kegan Paul, 1951); Bertrand Russell, *Human Knowledge, Its Scope and Limits* (London: Allen and Unwin, 1948); and Arthur Pap, *An Introduction to the Philosophy of Science* (New York: Free Press of Glencoe, 1962). Joan Robinson, *Economic Philosophy* (London: Watts, 1962), Ch. 4, is a highly readable brief account of Keynes's place in economic theory.

For another facet of Keynes's many-sided career, see *Essays and Sketches in Biography* (New York, 1956), a varied collection of Keynes's writings on economists, politicians, acquaintances, and himself.

## KEYSERLING, HERMANN ALEXANDER, GRAF VON (1880–1946)

Hermann Alexander, Graf von Keyserling, a German philosopher of life and man, was born in Kõnno, Estonia. He studied geology and other natural sciences at the universities of Dorpat, Geneva, Heidelberg, and Vienna. In 1902 Keyserling received his doctorate at Vienna, where, under the influence of Houston Stewart Chamberlain, he turned to philosophy. He spent the next few years in Paris, interrupting his stay, however, by several trips to England. In 1908, after two years in Berlin, Keyserling returned to Estonia to take over his ancestral estate at

Rayküll. He traveled frequently and in 1911 and 1912 took a trip around the world. The loss of his property after the Russian Revolution led to Keyserling's immigration to Germany. In 1920 he founded the School of Wisdom in Darmstadt. Further journeys to North and South America followed. The last years of his life were spent in the Austrian Tyrol.

Keyserling was not a systematic philosopher; instead, he presented brilliant observations, suggestive generalizations, and in vague outline, an image of man. To measure his work by traditional philosophy is to reject his view of the philosophic enterprise. Keyserling wanted to replace the traditional philosopher with the sage, to replace critical examination with immediate appreciation, and to replace the university with his School of Wisdom. He held that, instead of criticizing another position, one should try to empathize with it. His own *Travel Diary* furnishes an example of this approach. Keyserling reduced philosophy to an exercise with the thoughts of other ages and cultures in the hope that such play would lead the reader to an awareness of the spirit that underlies these thoughts. Truth, in the sense of adequacy to fact, was of little concern to Keyserling; intuitive appreciation alone counted. Keyserling used the word *polyphonic* to distinguish his thinking from "homophonic," traditional philosophy. Polyphonic thinking has no definite point of view and presents no definite theses. It is essentially rootless, an exercise with possibilities, designed to reveal a meaning that escapes all philosophic systems.

Keyserling's approach to philosophy bears witness to his understanding of man. Following Arthur Schopenhauer, Friedrich Nietzsche, Wilhelm Dilthey, Henri Bergson, and Eastern thought, he asserted the rights of life in the face of the modern overemphasis on the intellect. His insistence on the protean nature of man anticipated the existentialists' claim that existence precedes essence. Keyserling asked us to intuit, amid cultural and natural diversity, the spirit that finds only inadequate expression in each definite form. Those matters that are truly important cannot be thought clearly but can only be intuited. Critical philosophy was renounced; the philosopher had become an artist. The success of Keyserling's works, particularly of the *Travel Diary*, was symptomatic of the spiritual situation following World War I. Keyserling lent expression to the feeling that many of the traditional answers had become meaningless. But instead of deploring this spiritual homelessness, Keyserling made it a necessary condition of the full life: Ideally, man is a traveler.

## KHOMIAKOV, ALEKSEI STEPANOVICH (1804–1860)

Aleksei Stepanovich Khomiakov (1804–1860), was a Russian philosopher, theologian, poet, and writer, a founder of Slavophilism. Born into a wealthy Muscovite family of landed nobility, Khomiakov was educated in Moscow University. In his youth he took part in the Russo-Turkish War of 1828–1829. In his mature years, he preferred to live as a "private" gentleman in Moscow and on the family. He traveled abroad on two occasions: in 1825–1826 to Paris to study painting, and in 1847 to Germany and England. In the Russian social order he preferred the niche of an independent writer, poet, and playwright. Before his death, he revived The Society of the Lovers of Russian Literature (first founded at the beginning of the nineteenth century) at Moscow University, and served as its head. He died when he contracted cholera while treating peasants on his estate.

Khomiakov was a man of encyclopedic knowledge and diverse talents who brought his polemical style to bear on discussion in several fields in the humanities. Perhaps of greatest significance is his contribution to the philosophy of history. In his *Semiramida*, a three-volume work in the genre of universal history that he began writing in 1837 and continued writing to the end of his life, Khomiakov's goal is to explore the prehistory of nations. His conclusion is that culture as a whole is an expression of a higher spiritual principle—that is, religion. The vista of universal history represents the action upon humanity of cultural-religious archetypes, combined with ideas of freedom and necessity. There initially existed, according to Khomiakov, two types of nations: “conquering nations” and “agricultural nations”:

In accordance with their original character, conquering nations permanently preserve the sense of personal pride and contempt not only for those who are conquered but also for all those who are foreign ... When they are victorious, they repress those they have enslaved and do not mix with them; when they are defeated, they stubbornly resist the influence of the victors and preserve in their souls instincts engendered in them by epochs of former glory ... [By contrast] agricultural nations are closer to universally human principles. They have not been affected by the proud magic of victory ... Because of this they are more receptive to all things that are foreign. They do not experience aristocratic contempt for other nations; instead, they feel sympathy for all that is human. (1900)

Universal history, Khomiakov believes, unfolds according to the laws of the conflict between two opposite spiritual principles. Khomiakov calls the “agricultural” principle “Iranism,” and its opposite “Kushitism.” The spiritual history of humanity is viewed as the battle between Iranism and Kushitism. Such a conception was not entirely novel: Friedrich Schlegel had divided humanity into two opposed races—the Cainites and the Sethites—and in Hegel's *Philosophy of History* the Iranian “principle of light” is opposed to the Egyptian “principle of mystery.” What was new was that Khomiakov did not base this antinomy on the principle of “good-bad”; instead, he viewed Iranism and Kushitism as two equally necessary forces in history.

Further, Kushitism consists in analysis and rationalism, whereas Iranism tends toward a synthetic and integral reception of the world. Therefore, these two types of national psychology are equally natural. Based on neces-

sity, Kushitism engenders the state as a community based on convention. All of the civilizations of Kushitism were remarkable for being based on powerful state structures: Egypt, Babylon, China, Southern India. In contrast, Iranism proclaims the natural union of people and therefore rarely takes the form of a powerful political state. Thus, Khomiakov affirms that the historical process tends toward “the inevitable triumph of the Kushite principle” and to a “gradual decline of Iranism.” “Iranism ... has always been reestablished,” writes Khomiakov, “by the particular efforts of great minds, whereas Kushitism has crept into the historical process by the unceasing action of time and of the national masses.” If it happens that in Iranism there is an admixture of Kushitism, the latter is inevitably victorious (we find this, for example, in the history of ancient Greece and ancient Rome): Spiritual freedom must be absolute, and any concession to necessity leads to the death of freedom. The appearance of Christianity was the critical point of history: Christ represented a heroic effort to oppose the Kushitism of the world. But Christ's victory did not signify the victory of Iranism: Kushitism “closed itself up into the logic of the philosophical schools” (1900). And Hegelianism, which Khomiakov rejected, became the triumph of Kushitism in the nineteenth century. The Slavs belong to the Iranian type; that is what defines their place in history.

In Khomiakov's opinion, humans possesses the ability to strive toward being, toward God; but to preserve this striving, a special state is necessary: “true faith,” where the diversity of a person's spiritual powers are gathered into a living, ordered wholeness. From this point of view, faith—which is simultaneously knowledge and life (“life-knowledge”)—plays a special role in one's life.

Khomiakov's central conception is *sobornost'* (“catholicity,” integrity, inner fullness), which characterizes not only the Christian church but also the nature of humans, society, and the processes of cognition and creativity. *Sobornost* is the organizing metaphysical principle of all being; by the power of love it gathers diversity into a “free organic unity” (in this it is distinct from “collectivity”). It was Khomiakov who introduced the principle of *sobornost* into the Russian thought of the nineteenth century. He defines *sobornost* as “a free and organic unity, whose vital principle is the Divine grace of mutual love.” (1900) The foundation of *sobornost* is *grace*, a notion Khomiakov derives from Metropolita Ilarion's eleventh-century “Sermon on Law and Grace.” Khomiakov also insists that divine grace is likewise the foundation of the real church, which can only be known from within, through one's lived experience.

Khomiakov based his theological conception on personal *experience*; and therefore affiliation with the church essentially became a prerequisite for knowing reality in general. Thus, Khomiakov extends the doctrine of *sobornost* beyond theology to the entire domain of Russian culture. Khomiakov wrote that “Christianity—even with all its purity, with all its elevatedness over all human individuals—takes different forms for the Slav, for the Roman, and for the German” (1900). It often happens that the aggregate of national beliefs and convictions is reflected neither in “verbal monuments” nor in “monuments of stone,” and can be understood “only by looking at the entire life of a people, at its total historical development.” Khomiakov elaborated this broad conception in his theological works, which, for reasons of censorship, in his lifetime could only be published abroad.

Despite their apparently paradoxical nature, Khomiakov’s theological ideas were expressed at times with astonishing simplicity: “The Church is one, for two Churches do not exist”; “For there is one God and one Church, and there is no conflict or disharmony in her”; “The Church is not an institution”; “To assert that the Church is an authority is blasphemy.” One does not “belong” to the church the way one belongs to an organization. In the church, people live the way they live at home, in the bosom of their family, “humbly conscious of their weakness and subordinating the latter to the unanimous decision of the conscience of all in *sobornost*” (1900). And only this life in the church gives people freedom, which is the greatest good. In his letter “To the Serbians” (written just before his death), Khomiakov expressed his view on “the meaning and virtue of faith” as follows:

They are in great error, those who think that it [faith] is limited to the mere fulfillment of rituals or even to the relations of man to God. No: faith permeates the entire being of a man and all of his relations to his neighbor. As if with invisible threads and roots, faith grasps and is intertwined into all of a man’s feelings, convictions, and aspirations. Faith is like a better air, transforming the earthly principle in a man; or it is like a most perfect light, illuminating all the moral notions of a man and all of his opinions of other people and of the inner laws connecting him with them. Thus, faith is also a supreme social principle ... (1900)

Taking as his point of departure artistic intuition and “life-knowledge,” which he strove to reconcile with scientific knowledge, Khomiakov attempted to unite two

apparently incompatible sources: early patristics and ideas of Western romanticism and Western nature-philosophy. The organic principle of the interpretation of spiritual phenomena is evident not only in his ecclesiology, but also in his secular philosophy, as well as in his political and economic essays. The organic principle served as the foundation of his preference for gradual social development and conservatism. With the help of this principle Khomiakov sought to harmonize the Slavophile worldview with philosophical romanticism, bringing together such distinct categories as “the integrity of spirit,” “the fullness of perception,” and “the organic character of social development” (1900). This principle was also the source of his doctrine of *sobornost* and of the view of the church as the regulator of the entire life of the Orthodox Christian.

In Khomiakov’s social philosophy the opposition between *sobornost* and collectivity appears as the antithesis between *obshchina* (organic peasant community) and *druzhina* (organized “commune”), between “true brotherhood” and “conventional agreement.” In Khomiakov’s opinion, Russian history and Orthodox spirituality have manifested instances of true brotherhood, exhibited in the Russian peasant *obshchina*, which Khomiakov clearly idealizes, seeing in it the closest approximation to the social ideal. Petrine reforms, Khomiakov believes, led to the assimilation of “alien” principles by the Russian nobility and this, in turn, resulted in a split between the educated society and common people. Thus, in Khomiakov’s opinion, genuine folk culture in Russia could be created only by returning to original folk principles. Khomiakov devoted to this subject numerous articles that provoked a polemic both in Russia and in Europe in the 1840s. Russian thought began to assimilate Khomiakov’s heritage only many years after his death; his true stature became clear only at the end of the nineteenth century, when his major works were published (although not fully), and a Russian religious philosophy began to take shape.

### **Bibliography**

#### WORKS BY KHOMIAKOV

*Polnoye sobranie sochinenii* [Complete works]. 8 vols., edited by P. I. Bartenev and D. A. Khomyakov. Moscow, 1900–1911.

*Stikhotvoreniia i dramy* [Poems and plays], edited by B. F. Yegorov. Leningrad, 1969.

*Sochineniia* [Works]. 2 vols. Moscow, 1994.

*On Spiritual Unity: A Slavophile Reader*. Translated and edited by Boris Jakim and Robert Bird. Hudson, NY: Lindisfarne, 1998. This volume includes a translation of Khomiakov’s

“The Church Is One,” translations of three essays with “Remarks by an Orthodox Christian concerning the Western Communion,” and the third and fifth letters to William Palmer. This volume also contains an extensive bibliography of works by and about Khomiakov, as well as about the Slavophiles in general.

#### WORKS ABOUT KHOMIAKOV

- Berdiaev, N. A. A. S. *Khomiakov*. Moscow, 1912. Excerpts from Chapters 3, 4, and 8 of this work have been translated in Jakim and Bird, *On Spiritual Unity*. Hudson, NY: Lindisfarne, 1998.
- Gratieux, A. A. A. S. *Khomiakov et le mouvement slavophile*. 2 vols. Paris, 1939. Translated from the French as A. S. *Khomiakov and the Slavophile Movement*. 2 vols. Belmont, MA: 1982.
- Zenkovsky, V. V. *Istoriia russkoi filosofii*. 2 vols. Paris, 1948–1950. Translated by George L. Kline as *A History of Russian Philosophy*. 2 vols. (New York: Columbia University Press, 1953). See volume one of Kline, 180–205.

## KIERKEGAARD, SØREN AABYE (1813–1855)

Søren Aabye Kierkegaard, the Danish philosopher and religious thinker, frequently considered the first important existentialist, was the youngest son of Mikael Pederson Kierkegaard and Anne Sørensdatter Lund, born when his father was fifty-six years old and his mother was forty-four. His early childhood was spent in the close company of his father, who insisted on high standards of performance in Latin and Greek, inculcated an anxiety-ridden pietist devotion of a deeply emotional kind, and awakened his son’s imagination by continually acting out stories and scenes. Kierkegaard thus felt early the demand that life should be at once intellectually satisfying, dramatic, and an arena for devotion. Confronted with the Hegelian system at the University of Copenhagen, he reacted strongly against it. It could not supply what he

needed—“a truth which is true *for me*, to find *the idea for which I can live and die*” (*Journal*, August 1, 1835). Nor could contemporary Danish Lutheranism provide this. He ceased to practice his religion and embarked on a life of pleasure, spending heavily on food, drink, and clothes.

The melancholy that originated in his childhood continued to haunt him, however, and was increased by his father’s confiding in him his own sense of guilt for having somehow sinned deeply against God. For Kierkegaard, the question of how a man can be rescued from despair was consequently intensified. He resolved to return to his studies and become a pastor. He finished his thesis *On the Concept of Irony* (1841) and preached his first sermon. He became engaged to the seventeen-year-old Regine Olsen. But as he became aware of the uniqueness of the vocation that he felt within himself, he found himself unable either to share his life with anyone else or to live out the conventional role of a Lutheran pastor. For him, breaking off his engagement was a decisive step in implementing his vocation. (This cosmic view of the breach does not appear to have been shared by his young fiancée, whose natural hurt pride and rejected affection led to her marriage to Fritz Schlegel, afterward governor of the Danish West Indies.) From then on Kierkegaard lived a withdrawn life as an author, although he did involve himself in two major public controversies. The first followed his denunciation of the low standards of the popular Copenhagen satirical paper *The Corsair*. *The Corsair* in turn caricatured Kierkegaard unmercifully. The second sprang from his contempt for the established Danish Lutheran Church, and especially for its primate, Bishop Mynster, who died in early 1854. When Mynster’s about-to-be-appointed successor, Professor Hans Martensen, declared that Mynster had been “a witness to the truth,” Kierkegaard delivered a series of bitter attacks on the church in the name of the incompatibility he saw between established ecclesiastical conformism and the inward and personal character of Christian faith. He died shortly after refusing to receive the sacrament from a pastor. “Pastors are royal officials; royal officials have nothing to do with Christianity.”

Kierkegaard’s biography is necessarily more relevant to his thought than is the case with most philosophers, for he himself saw philosophical inquiry neither as the construction of systems nor as the analysis of concepts, but as the expression of an individual existence. The epitaph that he composed for himself was simply, “That individual.” From his own point of view, any verdict on his thought can only be the expression of the critic’s own existence, not a critical assessment which could stand or

fall according to some objective, impersonal standard. Hence all attempts at an objective evaluation of his thought were condemned by him in advance. He predicted and feared that he would fall into the hands of the professors. Moreover, the initial difficulty created by Kierkegaard's subjectivism is compounded by his style and manner of composition. Although he attacked G. W. F. Hegel, he inherited a large part of Hegel's vocabulary. Passages of great and glittering brilliance tend to alternate with paragraphs of turgid jargon. Both types of writing often prove inimical to clarity of expression. A great many of his books were written for highly specific purposes, and there is no clear thread of development in them. One device of Kierkegaard's must be given special mention: He issued several of his books under pseudonyms and used different pseudonyms so that he could, under one name, ostensibly attack his own work already published under some other name. His reason for doing this was precisely to avoid giving the appearance of attempting to construct a single, consistent, systematic edifice of thought. Systematic thought, especially the Hegelian system, was one of his principal targets.

#### THE SYSTEM, THE INDIVIDUAL, AND CHOICE

In Hegel's philosophical system, or rather in his successive construction of systems, the linked development of freedom and of reason is a logical one. Out of the most basic and abstract of concepts, Being and Nothing, there is developed first the concept of Becoming and the various phases of Becoming in which the Absolute Idea realizes itself during the course of human history. Each phase of history is the expression of a conceptual scheme, in which the gradual articulation of the concepts leads to a realization of their inadequacies and contradictions, so that the scheme is replaced by another higher and more adequate one, until finally Absolute Knowledge emerges and the whole historical process is comprehended as a single logical unfolding. It is this comprehension itself that is the culmination of the process, and this point was effectively reached for Hegel in his own philosophy. Thus, in *The Science of Logic* he was able to write that he was setting out not merely his own thoughts, but the thoughts of God—the idea of God being simply an anticipation of the Hegelian conception of the Absolute.

In the Hegelian view, both moral and religious development are simply phases in this total process. In *The Phenomenology of Mind*, Hegel described the moral individualism of the eighteenth century, for example, in terms of a logical progress from the hedonistic project of

a universal pursuit of private pleasure, through the romantic idealization of “the noble soul,” to the Kantian scheme of duty and the categorical imperative, trying to show how each was brought into being by the contradiction developed by its predecessor. In terms of the Hegelian view, an individual is essentially a representative of his age. His personal and religious views must give expression to his role in the total moral and religious development of humankind—a role that is imposed upon him by his place in the historical scheme. He can at best express, but not transcend, his age.

For Kierkegaard, Hegel dissolved the concreteness of individual existence into abstractions characteristic of the realm of concepts. Any particular conceptual scheme represents not an actuality but a possibility. Whether a given individual realizes this possibility, and so endows it with existence, depends upon the individual and not upon the concepts. What the individual does depends not upon what he understands, but upon what he wills. Kierkegaard invokes both Aristotle and Immanuel Kant in support of his contention that Hegel illegitimately assimilated concepts to individual existence; he praises in particular the manner of Kant's refutation of the Ontological Argument. But Kierkegaard, in his doctrine of the primacy of the will, is, in fact, more reminiscent of Quintus Septimius Florens Tertullian or Blaise Pascal.

Kierkegaard buttressed his doctrine of the will with his view of the ultimacy of undetermined choice. He maintained that the individual constitutes himself as the individual he is through his choice of one mode of existence rather than another. Christianity is not a phase in the total development of man's religious and moral ideas; it is a matter of choosing to accept or to reject God's Word. But choice is not restricted to this supreme decision; it is the core of all human existence. The Hegelian view that human existence develops logically within and through conceptual schemes is not merely an intellectual error. It is an attempt to disguise the true facts, to cast off the responsibility for choice, and to find an alibi for one's choices. Moreover, speculative system building falsifies human existence in another way, for it suggests that although those who lived prior to the construction of the system may have had to make do with a partial and inadequate view of reality, the arrival of the final system provides an absolute viewpoint. But according to Kierkegaard, such a viewpoint must be an illusion. Human existence is irremediably finite; its standpoint is incorrigibly partial and limited. To suppose otherwise is to yield to a temptation to pride; it is to attempt to put oneself in the place of God.

This conclusion is only a special case of Kierkegaard's general doctrine that his intellectual opponents are guilty fundamentally not of fallacies and mistakes, but of moral inadequacy. That Kierkegaard should have thought this not only reflects his unfortunate personality; it was a necessary consequence of his doctrine of choice. Another necessary consequence was his mode of authorship. On his own grounds, he cannot hope to produce pure intellectual conviction in his readers; all that he can do is to confront them with choices. Hence he should not try to present a single position. This explains Kierkegaard's method of expounding incompatible points of view in different books and using different pseudonyms for works with different standpoints. The author must conceal himself; his approach must be indirect. As an individual, he must testify to his chosen truth. Yet, as an author he cannot conceal the act of choice. From these views, it is apparent that Kierkegaard used a special concept of choice.

The essence of the Kierkegaardian concept of choice is that it is criterionless. On Kierkegaard's view, if criteria determine what I choose, it is not I who make the choice; hence the choice must be undetermined. Suppose, however, that I do invoke criteria in order to make my choice. Then all that has happened is that I have chosen the criteria. And if in turn I try to justify my selection of criteria by an appeal to logically cogent considerations, then I have in turn chosen the criteria in the light of which these considerations appear logically cogent. First principles at least must be chosen without the aid of criteria, simply in virtue of the fact that they are first. Thus, logical principles, or relationships between concepts, can in no sense determine a person's intellectual positions; for it is his choices that determine the authority such principles have for him. Is man then not even limited by such principles as those that enjoin consistency and prohibit contradiction? Apparently not. For even paradox challenges the intellect in such a way as to be a possible object of choice. The paradoxes that Kierkegaard has in mind at this point in his argument are those posed by the demands of ethics and religion. He is prepared to concede that in fields such as mathematics the ordinary procedures of reason are legitimate. But there are no objective standards where human existence is involved.

## THE AESTHETIC AND THE ETHICAL

In *Either/Or: A Fragment of Life* (1843), the doctrine of choice is put to work in relation to a distinction between two ways of life, the ethical and the aesthetic. The aesthetic point of view is that of a sophisticated and roman-

tic hedonism. The enemies of the aesthetic standpoint are not only pain but also, and above all, boredom. As Kierkegaard wrote of the protagonist of aestheticism in *Purify Your Hearts!*, "See him in his season of pleasure: did he not crave for one pleasure after another, variety his watchword?" The protagonist tried to realize every possibility, and no possibility furnishes him with more than a momentary actuality. "Every mood, every thought, good or bad, cheerful or sad, you pursue to its utmost limit, yet in such a way that this comes to pass *in abstracto* rather than *in concreto*; in such a way that the pursuit itself is little more than a mood..." But just because boredom is always to be guarded against, so its threat is perpetual. In the end, the search for novelty leads to the threshold of despair.

By contrast, the ethical constitutes the sphere of duty, of universal rules, of unconditional demands and tasks. For the man in the ethical stage "the chief thing is, not whether one can count on one's fingers how many duties one has, but that a man has once felt the intensity of duty in such a way that the consciousness of it is for him the assurance of the eternal validity of his being" (*Either/Or*, II, p. 223). It is important to note how intensity of feeling enters into Kierkegaard's definition of the ethical stage. He thought that what his own age most notably lacked was passion; hence one must not be deceived by the Kantian overtones of his discussions of duty. Kierkegaard's categorical imperative is felt rather than reasoned. He is an heir of such romantics as the Schlegel brothers in his attitude toward feeling, just as he is the heir of Hegel in his mode of argument. Kierkegaard is a constant reminder of the fact that those who most loudly proclaim their own uniqueness are most likely to have derived their ideas from authors whom they consciously reject.

In *Either/Or* the argument between the ethical and the aesthetic is presented by two rival characters: an older man puts the case for the ethical, a younger for the aesthetic. The reader, as we should expect, is allegedly left to make his own choice. But is he? The description of the two alternatives seems heavily weighted in favor of the ethical. The difficulty is that Kierkegaard wished *both* to maintain that there could be no objective criterion for the decision between the two alternatives, *and* to show that the ethical was superior to the aesthetic. Indeed, one difference between the ethical and the aesthetic is that in the ethical stage the role of choice is acknowledged. Kierkegaard frames this criticism of the man who adheres to the aesthetic: "He has not chosen himself; like Narcissus he has fallen in love with himself. Such a situation has certainly ended not infrequently in suicide." Remarks like

this suggest that in fact Kierkegaard thinks that the aesthetic fails on its own terms; but if he were to admit this, his concept of interested choice would no longer apply at this critical point. In one passage Kierkegaard asserts that if one chooses with sufficient passion, the passion will correct whatever was wrong with the choice. Here his inconsistency is explicit. According to his doctrine of choice, there can be no criterion of “correct” or “incorrect,” but according to the values of his submerged romanticism, the criterion of both choice and truth is intensity of feeling.

This inconsistency is not resolved; rather it is canonized in the thesis that truth is subjectivity. On the one hand Kierkegaard wants to define truth in terms of the way in which it is apprehended; on the other he wants to define it in terms of what it is that is apprehended. When inconsistency results, he is all too apt to christen this inconsistency “paradox” and treat its appearance as the crowning glory of his argument.

Kierkegaard is not consistent, however, even in his treatment of inconsistency. For he sometimes seems to imply that if the ethical is forced to its limits, contradiction results, and one is therefore forced to pass from the ethical to the religious. “As soon as sin enters the discussion, ethics fails ... for repentance is the supreme expression of ethics, but as such contains the most profound ethical contradiction” (*Fear and Trembling*, p. 147, footnote). What is this but Hegelianism of the purest kind?

Kierkegaard describes the transition from the ethical to the religious differently at different periods. In *Either/Or* the ethical sometimes seems to include the religious. By the time the *Concluding Unscientific Postscript* (1846) was written, the religious seems to have absorbed the ethical. In *Fear and Trembling* (1843), the passage from the ethical to the religious is even more striking than that from the aesthetic to the ethical. One of the heroes of this transition is Abraham. In demanding from Abraham the sacrifice of Isaac, God demands something that, from the standpoint of the ethical, is absolutely forbidden, a transgression of duty. Abraham must make the leap to faith, accept the absurd. He must concur in a “suspension of the ethical.” At such a point the individual has to make a criterionless choice. General and universal rules cannot aid him here; it is as an individual that he has to choose. According to Kierkegaard, however, there are certain key experiences on the margins of the ethical and the religious through which one may come to censure oneself as an individual. One such experience is the despair that Kierkegaard describes in *The Sickness unto Death*; another is the generalized fear and anxiety that is characterized in

*The Concept of Dread* (1844). Despair and dread point in the same direction. The experience of each forces the individual to realize that he confronts a void and that he is, in fact, responsible for his own sick and sinful condition. In the state of despair he is brought to recognize that what he despairs of are not the contingent facts (such as the loss of a loved one) that he claims to be the objects of his despair; the individual despairs of himself, and to despair of oneself is to see oneself confronting an emptiness that cannot be filled by aesthetic pleasure or ethical rule-following. Moreover, it is in order to become conscious that one has brought oneself to this point. In analyzing despair, we recognize guilt; so too with dread. Kierkegaard contrasts the fear that has a specific and identifiable object with the dread that is objectless; or rather he identifies the fear that is a fear of nothing in particular as a fear of Nothing. (The reification of negatives into noun phrases is typically Hegelian.) In the experience of dread I become conscious of my bad will as something for which I am responsible, and yet which I did not originate. Original sin is seen as a doctrine deduced from the analysis of experience.

In these works of Kierkegaard it is plain that the existentialist philosophy of choice is in some danger of being submerged in the romantic philosophy of feeling. But the testimony of feeling serves as a propaedeutic to the encounter with Christianity.

## CHRISTIANITY

Kierkegaard regarded his own central task as the explanation of what is involved in being a Christian. Apart from Christianity, the only religions he discusses are those of the Greeks and the Jews, and those only as a foil to Christianity. At first sight, Kierkegaard’s doctrines of choice and of truth stand in an uneasy relationship to his allegiance to Christianity. For surely Christianity has always claimed to be objectively true, independently of anyone’s subjective commitment, and Kierkegaard recognized this. “Not only does it [Christian revelation] express something which man has not given to himself, but something which would never have entered any man’s mind even as a wisp or an idea, or under any other name one likes to give to it” (*Journal*, 1839).

If what we believe depends on the believer’s own ultimate choice of rational criteria, then surely all beliefs have an equal moment, or rather equal lack of moment, for claiming objective truth. Kierkegaard, however, tried to evade this conclusion and continued to argue both that ultimate choice is criterionless and that one choice can be more correct than another.

Unfortunately, Kierkegaard never considered the issues raised by religions other than Christianity; for it would clarify our view of his position considerably if we could know what he would have said about an account of Islam or Buddhism that was logically parallel to his account of Christianity, in that it made their claims rest on a doctrine of ultimate choice. But the choices that Kierkegaard discusses are always those that might arise for an educated Dane of the nineteenth century. The foil to Christianity is not another religion, but secular philosophy.

This particular contrast is most fully elucidated in the *Philosophical Fragments* (1844), in which Kierkegaard begins from the paradox posed by Socrates in Plato's *Meno*. How can one come to know anything? For either one already knows what one is to come to know, or one does not. But in the former case, since one already knows, one cannot come to know; and in the latter case, how can one possibly recognize what one discovers as being the object of one's quest for knowledge? Plato's answer to this paradox is that in coming to know, we do not discover truths of which we had hitherto been totally ignorant, but truths of which we were once aware (when the soul pre-existed the body), but which we had forgotten. These truths lie dormant within us, and to teach is to elicit such truths. So Socrates makes the slave boy in the *Meno* aware that he knows geometrical truths which he did not know that he knew.

Suppose, however, Kierkegaard asks, that the truth is not within us already. It will then be the case that we are strangers to the truth, to whom the truth must be brought from outside. It will follow that the moment at which we learn the truth and the teacher from whom we learn the truth will not stand in a merely accidental relationship to us. On the Socratic view, one may learn geometry from this teacher or that, but the question of the truth of a geometric theorem is independent of the question from whom we learned it. Not so, on Kierkegaard's view. There are two possible conceptions of the truth that we must choose between, and the Socratic view represents only one alternative. It is important to note that in the *Philosophical Fragments* (1844) Kierkegaard does not say, as he says elsewhere, that one view of the truth is appropriate in matters of geometrical truth, but another is appropriate in matters concerning moral and religious truth. He speaks of two alternative views of the truth, which apparently cover every kind of subject matter, although for the rest of the book he discusses only religion.

Following Kierkegaard's preferred view of the truth, if the truth is not within us, it must be brought to us by a teacher. The teacher must transform us from beings who do not know the truth to beings who are acquainted with it. It is impossible to conceive any greater transformation, and only God could bring it about. But how could God become the teacher of man? If He appeared as He is, the effect on man would be to overawe him so that he could not possibly learn what God has to teach. (Kierkegaard cites the story of the prince in the fairy tale who could not appear to the swine girl as a prince because she would not have come to love him for himself.) Thus, Kierkegaard argues that if God is to be the teacher of man, He must appear in the form of a man, and more specifically, in the form of a servant. From the standpoint of human reason, the idea that God should come as a teacher in human form is an impossible paradox that reason cannot hope to comprehend within its own categories. But according to Kierkegaard, it is in encountering this paradox that reason becomes aware of the objective character of what it encounters.

To be a Christian is thus to subordinate one's reason to the authority of a revelation that is given in paradoxical form. The Christian lives before God by faith alone. His awareness of God is always an awareness of his own infinite distance from God. Christianity initially manifests itself in outward forms, and Kierkegaard reproaches Martin Luther for having tried to reduce Christianity to a pure inwardness—a project that has ended in its opposite, the replacement of inwardness by an ecclesiastical worldliness. Nonetheless, an inward suffering before God is the heart of Christianity.

As previously mentioned, Kierkegaard saw his own age as lacking in passion. The Greeks and the medieval monastics had true passion. The modern age lacks it, and because of this, it lacks a capacity for paradox, which is the passion of thought.

## CRITICISMS OF KIERKEGAARD

Kierkegaard used Friedrich Trendelenburg's exposition of Aristotle's logic to criticize Hegel. But he never took the question of the nature of contradiction seriously, and hence he never explained the difference, if any, between paradox (in his sense of the word) and mere inconsistency. But without such a clarification, the notion is fatally unclear. The lack of clarity is increased by Kierkegaard's failure at times to distinguish between philosophy, as such, and Hegelianism. Kierkegaard sometimes seems to have thought that any philosophy that

claims objectivity must consist solely of tautologies (*Papirer* III, B, 177).

His doctrine of choice raises at least two fundamental questions: Are there criterionless choices? And is it by such choices that we either can or do arrive at our criteria of true belief? Actual cases of criterionless choice usually seem in some way to be special cases. Either they are trivial, random selections (as of a ticket in a lottery) or they arise from conflicts of duties in which each alternative seems equally weighted. But none of these are choices of criteria. Such choices arise precisely at the point at which we are not presented with objective criteria. How do we arrive at such criteria? They appear to be internally connected with the subject matter of the relevant beliefs and judgment. Therefore we cannot choose our ultimate criteria in mathematics or physics. But what about morals and religion? Can one choose to consider the gratuitous infliction of pain a morally neutral activity? We are strongly inclined to say that an affirmative answer would indicate that the word *morally* had not been understood. But what is certain is that Kierkegaard's fundamental positions must remain doubtful until some series of questions such as this has been systematically considered. Kierkegaard himself never tried to ask them.

## Bibliography

### WORKS BY KIERKEGAARD

#### Texts

*Papirer*, 20 vols. Edited by P. A. Heiberg, V. Kuhr, and E. Torsting. Copenhagen: Gyldendal, 1909–1948.

*Samlede Vaerker*, 2nd ed., 14 vols. Edited by A. B. Drachmann, J. L. Heiberg, and H. O. Lange. Copenhagen, 1920–1931.

#### Texts in English Translation

The following listing is in order of original date of publication.

*Either/Or*, 2 vols. Vol. I, translated by D. F. Swenson and L. M. Swenson. Princeton, NJ, 1941. Vol. II, translated by W. Lowrie. Princeton, NJ, 1944.

*Fear and Trembling*. Translated by R. Payne. London: Oxford University Press, 1939. Also translated by W. Lowrie. Princeton, NJ: Princeton University Press, 1941.

*Repetition: An Essay in Experimental Psychology*. Translated by W. Lowrie. Princeton, NJ: Princeton University Press, 1941.

*Philosophical Fragments: Or, A Fragment of Philosophy*. Translated by D. F. Swenson. Princeton, NJ: Princeton University Press, 1936.

*The Concept of Dread*. Translated by W. Lowrie. Princeton, NJ: Princeton University Press, 1944.

*Stages on Life's Way*. Translated by W. Lowrie. Princeton, NJ, 1940.

*Concluding Unscientific Postscript*. Translated by D. F. Swenson and W. Lowrie. Princeton, NJ: Princeton University Press, 1941.

*The Sickness unto Death*. Translated by W. Lowrie. Princeton, NJ: Princeton University Press, 1941.

*The Point of View*. Translated by W. Lowrie. Princeton, NJ: Princeton University Press, 1941.

*Training in Christianity*. Translated by W. Lowrie. Princeton, NJ: Princeton University Press, 1944.

*Purify Your Hearts!* Translated by A. S. Aldworth and W. S. Fine. London: C. W. Daniel, 1937.

*For Self-Examination*. Translated by W. Lowrie. Princeton, NJ: Princeton University Press, 1941.

*The Present Age*. Translated by A. Dru and W. Lowrie. London: Oxford University Press, 1940.

*Christian Discourses*. Translated by W. Lowrie. London: Oxford University Press, 1939.

*Works of Love*. Translated by D. F. Swenson. Princeton, NJ: Princeton University Press, 1946.

*The Attack upon "Christendom."* Translated by W. Lowrie. Princeton, NJ: Princeton University Press, 1944.

*The Journals of Søren Kierkegaard: A Selection*. Edited and translated by A. Dru. Oxford: Oxford University Press, 1938.

## KIERKEGAARD, SØREN AABYE [ADDENDUM]

Søren Aabye Kierkegaard has been the subject of sharply rising scholarly interest since the mid-twentieth century.

In addition to several important works devoted to reexamining Kierkegaard's relation to G. W. F. Hegel, and numerous specialized treatments of key themes and problems in the authorship, newer studies have explored the significance of Kierkegaard's thought from literary, political, and historical viewpoints.

Niels Thulstrup (1967) traces the development of Kierkegaard's critical engagement with Hegel from 1835 to the conclusion of the pseudonymous authorship in 1846. Thulstrup carefully delineates the main sources of Kierkegaard's knowledge of Hegelian philosophy. This is an invaluable service, considering that much of what Kierkegaard knew about the German philosopher was actually gleaned from secondary sources. Of special interest are the Danish Hegelians, Johan Ludvig Heiberg and Hans Lassen Martensen, and the anti-Hegelians, Frederik Christian Sibbern and Poul Martin Møller. Thulstrup also examines the influence of important German writers such as Johann Erdmann, Johann Gottlieb Fichte, Friedrich von Schelling, Adolf Trendelenburg, Marheinecke, and Werder. The notable tendency in this work to read Hegel through a Kierkegaardian lens leads the author to conclude that the two "have nothing in common as thinkers." This conclusion, however, has been challenged by other commentators who claim to find deeper parallels in their thought.

Several such parallels are noted by Mark C. Taylor (1980). Taylor points out, for instance, that both thinkers see the spiritlessness of modernity as the chief obstacle to selfhood and that both attempt to recover spirit through a process of "aesthetic education." For Hegel, however, spiritlessness represents a form of self-alienation that can be overcome only by a reconciliation of self and other, a mediation of the individual's personal and social life; while for Kierkegaard, the threat to spirit lies in the modern tendency to objectify and systematize, to dissolve the distinction between the individual and "the crowd." Taylor argues that Kierkegaard's exclusive emphasis on the individual is ultimately self-negating, since the self is never merely the self but bears a necessary and internal relation to the other. Hegel's relational conception of selfhood is thus shown to be more adequate and more comprehensive than Kierkegaard's, which "necessarily passes over into its opposite—Hegelian spirit" (p. 272). There remains a genuine question, however, about whether Kierkegaard's critique of "the crowd" precludes the possibility of a genuine human community in which individual responsibility is preserved.

Stephen N. Dunning (1985) goes even further than Taylor, suggesting that a relational conception of selfhood

is implicit in the dialectical structure of Kierkegaard's writings. Dunning argues that the solitude of the self is "always a moment in a development that embraces interpersonal relations that can be contradictory (the aesthetic stage), reciprocal (the ethical stage), or paradoxically both incommunicable and reciprocal (the religious stage)" (pp. 248–49). According to this reading the *Postscript* describes a religious dialectic that culminates in a paradoxical unity of the self as both "other to itself (in sin) and restored to itself by God" (p. 249), and at the same time related to the entire community of Christians by a deep bond of sympathy. In this way, the theory of stages confirms the Hegelian insight that the solitary self is incomprehensible apart from the relational structures that give it meaning. It has been noted, however, that the formal similarities between Kierkegaardian and Hegelian dialectic may mask important conceptual differences noted by Thulstrup and Taylor.

Three studies of Kierkegaard's moral and religious philosophy deserve special mention. The first is Gregor Malantschuk's excellent study (1968). Working mainly from the journals, Malantschuk shows that the authorship is governed by a qualitative dialectic, which is aimed at illuminating the subjective dimensions of human existence, while the later polemical writings make use of a quantitative dialectic, which invokes the visible degradation of Christ as a judgment on Christendom. The dialectical method is thus seen to be the golden thread that runs through all of Kierkegaard's writings and places the individual works in the larger context of his avowed purpose as a religious author.

C. Stephen Evans's study of the *Fragments* and *Postscript* (1983) is widely recognized as one of the best general introductions to the Climacus writings available in any language. Though the book is written for the "ordinary" reader rather than the specialist—there is no critical engagement with the secondary literature—students and scholars alike have found it immensely useful for its coherent presentation of the main themes in Kierkegaard's religious philosophy, including his complex use of irony and humor in connection with the theory of indirect communication. The clarity of Evans's exposition is unsurpassed, even by his 1992 book, which returns to many of the issues addressed in the earlier work.

M. Jamie Ferreira (1991) explores one of the most difficult conceptual problems in the authorship: the nature of religious conversion. Challenging volitionalist and antivolitionalist accounts of the Kierkegaardian leap, Ferreira reconceptualizes the transition to faith as a "reorienting, transforming, shift in perspective" (p. 57).

Central to this account is the concept of surrender, which is explicated in terms of the imaginative activities of suspension and engagement. Based on this analysis, Ferreira offers a compelling refutation of the popular but mistaken assumption that Kierkegaard viewed ethical and religious choice as criterionless and hence immune to critical appraisal. Her analysis suggests rather that the more wholeheartedly one chooses, the more likely one is to discover whether one has made the wrong choice. On this reading passionate engagement is not meant to guarantee that one will continue in a choice no matter what, but it does ensure that one will experience more fully what is implied by a choice. In this way passionate engagement is seen to facilitate the possibility of critical appraisal.

Louis Mackey (1971) uses the tools of literary criticism to explore the complex relation between the literary and philosophical dimensions of Kierkegaard's authorship. Mackey argues that even the most philosophical of Kierkegaard's books, the *Fragments* and *Postscript*, call into question the very nature of the philosophical enterprise. His use of literary devices, intended to create a poetic indirection, always leave the reader somewhere between assertion and irony. Mackey goes on to make a more general point about the relation between philosophy and poetry, observing that "all humane philosophy is a poetic and for that reason an indirect communication" (p. 295). Indeed, the philosophers of Western tradition have in this sense, he claims, "always been poetic philosophers" (p. 295). This theme is developed further in Mackey (1986), which attempts to situate Kierkegaard in relation to current trends in deconstructionist thought and literary practice.

Bruce Kirmmse (1990) traces the political, economic, and social history of Denmark from 1780 to 1850, giving us a detailed picture of the cultural milieu in which Kierkegaard lived and wrote. Focusing on the boundaries between the public and the private, between politics and religion, Kirmmse lays a foundation for understanding the connection between Kierkegaard's critique of society and his attack on the established church. The exposition is facilitated by a discussion of Kierkegaard's important religious writings, which are frequently overlooked in major surveys of his thought. Until recently Kierkegaard's social and political views had received scant attention in the secondary literature. Other notable discussions can be found in chapters 8 and 9 of Alastair Hannay (1982) and in Merold Westphal (1987).

## KILVINGTON, RICHARD

(c. 1302–1361)

Richard Kilvington, Master of Arts (c. 1325) and Doctor of Theology (c. 1335) at Oxford, was a member of Richard de Bury's household, later becoming archdeacon and finally dean of Saint Paul's Cathedral in London. Along with Thomas Bradwardine, Kilvington formed the first academic generation of the school known as the "Oxford Calculators." All of Kilvington's philosophical works—*Sophismata* and *Quaestiones super De generatione*

*et corruptione* (written before 1325), *Quaestiones super Physicam* (c. 1326) and *Quaestiones super libros Ethicorum* (before 1332)—and his theological questions on Lombard's *Sentences* (c. 1334) stem from lectures at Oxford. In his *Physics*, Kilvington found an original way to apply the Euclidean theory of ratios to a new formula relating speeds, forces, and resistances in motions. Because the new rule avoided a serious weakness in Aristotle's theory of motion, nearly everyone adopted it, including the most famous Oxford Calculator, Thomas Bradwardine, in his renowned treatise on velocities in motions, written in 1328.

Following William of Ockham, Kilvington refuted the Aristotelian prohibition against *metabasis* and was convinced that mathematics is useful in all branches of scientific inquiry. He made broad use of the most popular fourteenth-century calculative techniques to solve physical, ethical, and theological problems. Four types of measurement are present in his works: by limits, that is, by the first and last instants of continuous processes, and by the intrinsic and extrinsic limits of capacities of passive and active potencies; by latitude or degree of forms, to measure intensive changes; by a calculus of compounding ratios, to determine speed of motion; and by one to one correspondence, to compare different infinities. Having adopted Ockham's position of ontological minimalism, Kilvington claimed that absolutes—that is, substances and qualities—are the only subjects that change and therefore all other terms, such as “motion,” “time,” “latitude,” or “degree,” are modes of speech. Accordingly, he contrasted things that are really distinct with things that are merely distinct rationally or in imagination. Because imaginable means possible—that is, not self-contradictory—in physics Kilvington discussed *secundum imaginationem* (according to imagination) counterfactual cases, such as the rectilinear motion of the earth or motion in a vacuum, and pondered questions that would never arise from direct observation, because the structure of nature can only be uncovered by highly abstract analysis.

Like many Oxford Calculators, Kilvington refrained from including God in the speculations of natural science. However, like almost everyone in the fourteenth-century, he distinguished between God's absolute power (*potentia Dei absoluta*) and ordained power (*potentia Dei ordinata*). The laws of nature reflect God's ordained power. Thanks to his absolute power and will, a presently active power, God might intervene to change or contradict the order of things that he had established. Therefore, it is possible for the past to have been otherwise,

because all past events are contingent. Kilvington's teaching on logic, natural philosophy, and theology was markedly influential both in England and elsewhere in Europe. He inspired both the next generation of Oxford Calculators and important Parisian masters such as Nicolas Oresme.

## KILWARDBY, ROBERT

(c. 1210–1279)

Robert Kilwardby was an English Dominican. He was a master of arts at the University of Paris between 1237 and 1245 and a student and master of theology at Blackfriars, Oxford, between 1248 and 1261. He then became prior provincial of the English Dominicans and in 1273 he was consecrated archbishop of Canterbury. In 1278 he entered the papal service as cardinal-bishop of Porto and Santa Rufina; he died in Viterbo in 1279.

Kilwardby had a profound influence on thirteenth- and fourteenth-century Scholasticism. In general he tried to promote the philosophical views of Augustine in a time when Aristotle's influence was becoming more and more important. As archbishop of Canterbury he even tried to suppress Aristotelian views by condemning thirty errors in philosophy in the so-called Oxford condemnation of 1277.

His most important and long-lasting influence, however, was in logic. During his Paris years he commented on the whole *Organon* of Aristotle, wrote two *Sophismata*

(*Sophismata grammaticalia* and *Sophismata logicalia*) and also several books on grammar. His commentary on *Priscianus minor* is the most important. During this incredibly productive time of his life he also wrote a commentary on Porphyry's *Isagoge*, and perhaps the earliest commentary on Aristotle's *Nicomachean Ethics*.

Very few of these works have been studied, and most of them still remain in manuscripts. The logical work that in recent years has received most attention is his commentary on Aristotle's *Prior Analytics*. As an exposition of Aristotle's theory of the syllogism, the commentary maintains an extraordinarily high degree of fidelity to Aristotle's text. As part of his overall project of constructing faithful interpretations of Aristotle, Kilwardby aims in his commentary to produce an accurate interpretation of Aristotle's modal syllogistic. The commentary is significant because it appears to be the origin, in the Latin world, of a tradition in which Aristotle's essentialist metaphysics is deployed in the interpretation of his syllogistic.

Kilwardby's work makes use of a number of technical concepts in a very disciplined way. These include notions of a *per se* term and a *per se* necessity and two concepts of *simpliciter* predication. The analysis of these concepts requires both the notion of an essential property and the notion of a necessary proposition. For example, a term is *per se* provided that it is necessary that, whatever it is, it is essentially that. *Per se* terms are contrasted with *per accidens* terms like *walking* for which nothing that is walking is essentially walking. Hence, a sentence like "Every *B* is necessarily *A*" expresses a *per se* necessity provided that (i) "*B*" is a *per se* term and (ii) "*A*" is a *per se* term and (iii) "Every *B* is *A*" is a necessary proposition.

The most important works from Kilwardby's tenure in Oxford are the *De ortu scientiarum* (1250), which is a classification of the sciences and was intended to be an introduction to philosophy, and his questions on the *Sentences* of Peter Lombard from around 1256. The *Sentence*-commentary is influenced by Richard Rufus of Cornwall. Kilwardby also produced smaller but very interesting treatises on relation, on time, and on imagination during this period.

## Bibliography

### PRIMARY WORKS

*De natura relationis* (On relation, c. 1256–1261), edited by L. Schmücker, Brixen: L. Schmücker, 1980. A late work on relations.

*De ortu scientiarum* (On the origin of science, c. 1250), edited by A. G. Judy. *Auctores Britannici Medii Aevi* 4, London: British Academy, 1976. Kilwardby on natural philosophy.

*De spiritu fantastico* (On imagination, c. 1256–1261). *On Time and Imagination: De tempore, De spiritu fantastico*, edited by P. O. Lewry. *Auctores Britannici Medii Aevi* 9. Oxford: Oxford University Press for the British Academy, 1987. A late work on imagination.

*De tempore* (On time, c. 1256–1261). *On Time and Imagination: De tempore, De spiritu fantastico*, edited by P. O. Lewry. *Auctores Britannici Medii Aevi* 9. Oxford: Oxford University Press for the British Academy, 1987. A late work on time.

*In donati artem maiorem III* (Commentary on Donatus, c. 1237–1245), edited by L. Schmücker. Brixen: Typographia A. Weger Fund, 1984. Commentary on the grammatical work of Donatus.

*In libros Priorum Analyticorum expositio* (Exposition on the books of the *Prior Analytics*, c. 1240). Printed under the name Aegidius Romanus, Venice 1516. Reprinted Frankfurt 1968. Commentary on the *Prior Analytics*.

*Notule libri prisciani de accidentibus* (Commentary on *De accidentibus*, c. 1237–1245), edited by P. O. Lewry, "Thirteenth-Century Teaching on Speech and Accentuation: Robert Kilwardby's Commentary on *De accidentibus* of Pseudo-Priscian." *Medieval Studies* 50 (1988): 96–185. Commentary on Priscian.

*Quaestiones in librum [primum/secundum/tertium/quartum] Sententiarum* (Questions of the [first/second/third/fourth] book of the *Sentences*) [c. 1256]. *primum*, edited by J. Schneider; *secundum*, edited by G. Leibold; *tertium*, part 1, *Christologie* (Christology), edited by E. Gössmann, and part 2, *Tugendlehre* [Virtue], edited by G. Leibold; *quartum*, edited by R. Schenk. Veröffentlichungen der Kommission für die Herausgabe ungedruckter Texte aus der mittelalterlichen Geisteswelt. Munich: Verlag der Bayerischen Akademie der Wissenschaften, *primum*, 1986; *secundum*, 1992; *tertium*, 1982 (part 1), 1985 (part 2); *quartum*, 1993. Questions on the *Sentences* of Peter Lombard.

### SECONDARY WORKS

Braakhuis, H. A. G. "Kilwardby versus Bacon? The Contribution to the Discussion on Univocal Signification of Beings and Non-Beings found in a Sophism attributed to Robert Kilwardby." In *Medieval Semantics and Metaphysics*, edited by E. P. Bos, 111–142. *Artistarium supplementa* 2, Nijmegen: Ingenium, 1985. An introduction to Kilwardby's theory of meaning.

Celano, A. J. "Robert Kilwardby and the Limits of Moral Science." In *Philosophy and the God of Abraham*, edited by R. James Long, 31–40. Toronto: Pontifical Institute of Mediaeval Studies, 1991. Study of Kilwardby's moral philosophy.

Ebbesen, S. "Albert (the Great?)'s Companion to the Organon." In *Albert der Grosse. Seine Zeit, sein Werk, seine Wirkung*, edited by A. Zimmerman, 89–103. Berlin: Walter de Gruyter, 1981. Ebbesen shows that Albert the Great copies Kilwardby's *Prior Analytics* commentary.

Gál, G. "Robert Kilwardby's Questions on the Metaphysics and Physics of Aristotle." *Franciscan Studies* 13 (1953): 7–28. On the attribution of a set of questions on metaphysics and physics.

Lagerlund, Henrik. *Modal Syllogistics in the Middle Ages*.

Leiden: Brill, 2000. Chapter 2 contains a detailed study on Kilwardby's modal syllogistics.

Lewry, P. Osmund. "The Oxford Condemnation of 1277 in Grammar and Logic." In *English Logic and Semantics from the End of the Twelfth Century to the Time of Ockham and Burleigh*, edited by H. A. G. Braakhuis and L. M. de Rijk, 235–278. *Artistarium supplementa* 1, Nijmegen: Ingenium, 1981. An account of the implications for logic of the 1277 condemnation.

Lewry, P. Osmund. "Robert Kilwardby on Imagination: the Reconciliation of Aristotle and Augustine." *Medioevo* 9 (1983):1–42. Discussion of Kilwardby's view of the soul.

Lewry, P. Osmund. "Robert Kilwardby's Commentary on the *Ethica nova* and *Vetus*." In *L'homme et son univers au moyen-âge*, edited by C. Wedin, 799–807. *Philosophes médiévaux* 27, Louvain-la-Neuve: Editions de l'Institut Supérieur de Philosophie, 1986. A summary of Kilwardby's views on ethics.

Lewry, P. Osmund. "Robert Kilwardby's Writings on the *Logica Vetus* Studied with Regards to Their Teaching and Method." Ph.D. diss. University of Oxford, 1978. Still the standard text for a discussion of Kilwardby's logic.

*Henrik Lagerlund (2005)*

## KIM, JAEGWON

(1934–)

Jaegwon Kim is a Korean American philosopher born in Taegu (Korea) and educated at Seoul National University, Dartmouth College, and Princeton University. He has taught at Cornell University, University of Michigan, and Brown University, among other institutions. Kim's decisive contributions to philosophy range mainly over many central topics in the philosophy of mind and metaphysics but extend to philosophy of science and epistemology as well. Kim's most influential views in metaphysics and his early stance about the mind were defended in essays published from the early 1970s to the early 1990s and collected in the book *Supervenience and Mind* (1993). His later views on the mind are defended in two books: *Mind in a Physical World* (1998) and *Physicalism, or Something Near Enough* (2005).

In metaphysics, Kim's most crucial influence has been in event theory and the nature of dependence relations, including causation and supervenience. Kim's *property exemplification* account of events is regarded, together with Donald Davidson's account, as one of the two main contenders in the field. According to Kim (1993, essays 1 and 3) an event is not a basic component of ontology; it is a complex entity constituted by a property *P* (or a relation) exemplified by an object *O* (or n-tuple of objects) at a time *t*. If events are the *relata* of

causal relations and causal relations require nomological connections (two widespread assumptions that Kim supports), Kim's fine-grained account of events has the advantage of indicating, in a causal relation, which feature of the *cause event* (its constitutive property) is nomologically connected with which feature of the *effect event* (its constitutive property).

Kim argues that just as causation (about which he is a regularist and a realist) constitutes the diachronic connection among phenomena, there are other metaphysically significant cementing relations that are noncausal (1993, essay 2). One of those relations is particularly important: supervenience, a synchronic dependence relation that connects properties in a given *supervenient* level with properties of a more basic level so that the most basic ones fully determine the supervenient ones. Kim is widely regarded as the leading theorist on supervenience, having carefully distinguished between several types of supervenience relations (e.g., weak, strong, and global) their consequences for reduction and for naturalist ontologies, having applied the notion to a general ontological stance he calls the *layered view of reality* and having used the concept to analyze perennial issues in the mind-body problem (1993, essays 4 to 10).

In the philosophy of mind Kim's work can be divided in three phases. In the early 1980s he defended a nonreductive naturalist/physicalist model of mental causation called supervenient causation. Given two mental properties *M* and *M\** that supervene, respectively, upon physical properties *P* and *P\**, if *P* causes *P\**, *M* superveniently causes *M\**. And if *M* supervenes on *P* and *P* causes *P\**, *M* superveniently causes *P\**. Supervenient causation is not outright causation but Kim claimed it was sufficient to endow mental properties with causal efficacy since these properties supervene on properties involved directly in causal processes. Supervenience plays here the double role of articulating the naturalist commitment and accounting for an acceptable (yet somewhat deflationary) approach to mental causation. The model is nonreductive because despite the causal powers of mental properties being reduced to those of their bases, the properties themselves are not reduced since supervenience does not imply identity.

In the late 1980s Kim produced several famous attacks against different forms of nonreductive physicalism (1993, essays 13 to 17; 1998, chapters 2 and 3). Against Davidson's anomalism, Kim argues that the view implies that the fact that an event falls under a mental kind is a causally irrelevant fact. Against functionalism, he claims that its multiple realizability thesis implies *local*

reductions and as such does not have the intended nonreductive force. More generally, he develops an argument against all forms of nonreductive physicalism called the causal/explanatory exclusion argument. For a physicalist every physical event has to have a complete physical cause. Kim shows by analyzing and ruling out scenarios that go from partial causes to causal overdetermination that within that framework, we cannot attribute a causal role to the mental unless it is identified with the physical, turning nonreducible mental properties into epiphenomena. Since he also defends the principle that without causal efficacy an entity cannot be real, every form of nonreductive physicalism turns into an eliminativist view. It soon became evident to Kim as much as to his critics that his supervenient causation model is also an easy target of the exclusion argument. Additionally, Kim has lost faith on the explanatory power of the supervenience relation in general, and in particular as a tool for analyzing mental causation. If supervenience is only a superficial relation of property covariation between the mental and the physical and it is itself in need of explanation, it cannot articulate a deep explanatory relation between the mental and the physical.

With this background Kim developed in the 1990s an approach to the mental that can be called functional reductionism (1998, 2005). The proposal consists of grounding the mind-body supervenience relation on the realization relation proposed by functionalism. Mental properties are second-order properties defined over a set of first-order properties that satisfy a given causal/functional condition and thus are eligible as realizers of such second-order properties. Given a mental property *M* we attempt to construct a functionalization of it in which *M* is characterized in terms of its typical causes and effects. This functionalization of a property is, Kim argues, sufficient for reduction (under a non-Nagelian, functional account of reduction). Reductive functionalization explains why there are the dependence relations there are and provides ontological simplification by identifying the second-order property with an exhaustive disjunction of all its realizers or else, according to Kim, we may decide to recognize only second-order *concepts* or *predicates* but not second-order properties. Still, Kim thinks that the qualitative properties of experience, unlike the rest of mental states, cannot be functionalized. Since, according to Kim, they are not reducible through type identification with neural-biological properties either, we have to accept them as a *mental residue* that prevents us from embracing a fully generalized physicalism.

Within philosophy of science, Kim's most significant contribution is a sophisticated view of what he calls the

*metaphysics of explanation* that combines explanatory realism and pluralism (1989, 1994). According to realism, explanations are grounded in structural, *world-cementing* objective relations between the events referred to by the *explanandum* and the *explanans*. According to pluralism there are, in addition to causal explanations, explanations tied to noncausal, structural dependence relations (such as supervenience). This view can be seen to accord well with Kim's views regarding causal realism and the importance of noncausal relations, and explicitly includes the claim that pluralist realism explains via unification the cognitive value of explanations. In epistemology, Kim has produced an influential critique of Willard Van Orman Quine's naturalized epistemology (1993, essay 12). While defending epistemological naturalism in the sense that epistemic properties supervene upon factual, nonepistemic properties, he criticizes Quine's purely nomological, nonnormative approach to studying how evidence relates to beliefs. The gist of Kim's argument is that the very concept of knowledge disappears if we abandon the normative notion of justification.

## KING, MARTIN LUTHER (1929–1968)

Martin Luther King Jr. was born in 1929 in Atlanta, Georgia. He attended Morehouse College, Crozer Theological Seminary, and Boston University, where he earned a doctorate in philosophical theology. In 1964, he was awarded the Nobel Peace Prize. He was assassinated in Memphis, Tennessee, in 1968.

King first gained international attention when, after completing his doctoral studies and becoming pastor of the Dexter Avenue Baptist Church in Montgomery, Alabama, he led the fight to desegregate public transportation in Montgomery. His strategy was nonviolent passive resistance. The faith that underlay that strategy was that white Americans could be persuaded by black suffering and moral argument to agree on the injustice of laws requiring the segregation of the races. The essentials of that faith are eloquently summarized in his frequently reprinted "Letter from Birmingham City Jail," and in his arguably most famous speech, "I Have a Dream." In that letter and speech King stressed his vision of the "beloved community," his vision of the "color-blind society," his conviction that injustice could be cured if exposed to the light of human conscience, and his conviction that every person has a duty to love one's enemies, and to avoid violence.

However, even in these works, King was not as optimistic or as completely reliant on white conscience as many have apparently thought him to be. For example, as his essay on civil disobedience reveals, his strategy of civil disobedience was designed not only to appeal to white conscience, but also to bring economic pressure on merchants. It is therefore a mistake to identify his theory with that of John Rawls, although Rawls himself stated that the two theories are similar.

King's more pessimistic or at least realistic views emerged more clearly in later speeches. Probably he was influenced by nationalists like Malcolm X and Stokely Carmichael (later known as Kwame Ture.) Certainly he admitted that he had started seeing his dream turning into a "nightmare," and that most Americans were "unconscious racists." Like Frederick Douglass before him, King concluded that moral suasion alone would not

succeed in moving the white political establishment to implement the needed reforms, and that black people and their allies should therefore seek political power, though unlike Douglass he never advocated violence. In King's mature philosophy this new turn coincided with a greater emphasis on the poverty of many black Americans, and the relation of their plight to America's behavior in the international arena. King believed that the injustice of that behavior was being then revealed dramatically by the war in Vietnam and his criticisms of that war, together with his evidently growing sympathies for socialism lost him many allies. King's last speech, "I See the Promised Land," seems to contain premonitions of his assassination on the next day.

Unfortunately, as scholars of King's philosophy have noted, conservatives of the late twentieth and early twenty-first centuries have skillfully misused King's vision of a future color-blind society, especially his longing for a nation in which his four little children "will not be judged by the color of their skin but by the content of their character," to oppose color-conscious means like affirmative action for achieving such a nation.

## KIREEVSKII, IVAN VASIL'EVICH (1806–1856)

Ivan Vasil'evich Kireevskii, Russian literary critic and religious philosopher, was born in Moscow in a family of the old nobility related to the important poet Vasilii Zhukovskii (1783–1852). Kireevskii's father died in 1812 after contracting typhus in a hospital he founded for wounded soldiers. After his father's death, the young boy's education was largely guided by Zhukovskii, who did much for the development of Kireevskii's literary talent. Zhukovskii repeatedly affirmed, with total sincerity, that his young relative could become a fine writer. In 1823 Kireevskii became a member of the *Obshchestvo liubomudrov* (Society of the lovers of wisdom), organized by Dmitrii Venevitinov and Prince Vladimir Odoevskii for the study of German philosophy, especially Schelling. To complete his education, Kireevskii went abroad in 1830. In Germany he attended the lectures of Hegel, Schelling, and Schleiermacher. When he returned to Russia, he began to publish the journal *Evropeets* (The European, 1832), which was soon prohibited by the government. The orientation of the journal was somewhat "pro-Western": Kireevskii had set himself the task of synthesizing Western-European and Russian thought.

Kireevskii's further evolution was closely connected with Slavophilism. In 1845, for a period of time he was the editor of the Slavophile journal *Moskovitianin* (The Muscovite); and later he expounded his religious-philosophical ideas in the collection of articles *Moskovsiii Sbornik* (Moscow collection, 1852), published by the Slavophile circle. In the final years of his life, Kireevskii was working on a course of philosophy in which his intent was to clearly display the distinguishing characteristics of the Russian philosophical tradition. The course was not completed. Kireevskii's collected works were first published in 1861, in two volumes.

The central idea of Kireevskii's philosophy was the integrity of the spirit: A human being can remain a person as long as he preserves in himself the unity of his "mind and heart," the "integrity" of his consciousness, of his "inner organization." Meanwhile, Kireevskii's epistemological theories were closely connected with his socio-

historical views. Only by attaining a harmonious "integral thinking" can the person and society avoid the two extremes: the ignorance that separates a nation from the "living communion of minds" and "abstract logical thinking" (rationalism) that fragments the integrity of the spirit into its separate elements (Kireevskii 1984, pp. 221–222).

Kireevskii tended to associate what he perceived as the limitations of Western society primarily with the on-sidedness of rationalism. He viewed Hegel as the final and supreme peak of Western rationalistic thought, continuing the tradition of Aristotle. In assessing various attempts to overcome rationalism in Europe (Schelling), Kireevskii considered that their failure was predetermined: Philosophy depends on the "character of the dominant faith," but in the Catholic-Protestant West the two dominant Christian faiths are, according to the Slavophile assessment, profoundly rationalistic. Kireevskii's own allegiance was to Orthodox theism, and he viewed the future "new" philosophy as a harmony of reason and Orthodox faith based on feeling.

Kireevskii thought that Western culture had already passed the highest point of its development and exhausted its potential. In his article "On the Nature of European Culture and on its Relationship to Russian Culture," Kireevskii writes that contemporary Western man "fragments his life into separate strivings or tendencies"; in "one corner of his heart there lives the religious sense; in another corner, separately, there live the powers of the intelligence and exertions related to everyday occupations; in a third corner there lives the desire for sensuous pleasures; in a fourth there lives moral feeling related to family life; and in a fifth there lives the desire for personal gain" (Kireevskii 1984, pp. 203, 229). That is, the souls of contemporary Westerners is mosaiclike, fragmented.

According to Kireevskii, such a transformation of human consciousness into a "calculating machine" will lead, in the final analysis, to the triumph of the lower desires, the instincts, where people will shut themselves up in their physical persons and desire only material comfort. It is precisely for this reason that Kireevskii began to seek the sources of a "new" and "young" philosophy, which was destined to supplant rationalism, overcome the fragmentedness of man's being, and lead to the "integral spirit." Kireevskii turned his glance toward the Russo-Slavic culture, in which, in his opinion, Orthodoxy was the principle that unified all spheres of life, combining spirit, reason, conscience, will, and feeling into a "thinking that believes." This thesis of Kireevskii's was, not without justification, called "epistemological utopi-

anism” by Vasilii Zenkovsky, the well-known historian of Russian philosophy.

Kireevskii attempted to answer the question of why the European and Russian cultures were separated as it were by an invisible wall. In doing so, he defined the sources of the European culture of his day. He identified three such principles or “elements”: (1) the influence of the Christian religion; (2) the spirit of the barbarian nations that destroyed the Roman Empire; and (3) the remnants of the ancient world, of classical scholarship. Kireevskii analyzed these principles of Western civilization and arrived at the conclusion that the development of Russia lacked the classical heritage of the ancient world.

This “lack of the classical world” (Kireevskii 1984, p. 72) was, in his opinion, the reason why the influence of the Orthodox Church on Russia was not as strong as the influence of the Roman Catholic Church on the Western European countries, the Roman Church having experienced the enormous influence of the Roman government and Roman law on its organization. As a result, the Christian church in Russia could not become a force that would unite spiritually and politically fragmented Russia, which because of this fragmentation fell subject to the Tatar Yoke for several centuries. On the one hand, without a spiritual center (the kind of center that the Vatican was for fragmented Europe), Russia could be unified not spiritually but only materially (in other words, not in a spiritual but in a material *sobornost*), and this material unification took many centuries. On the other hand, the peculiar character of the development of Russia led to a situation where the Russo-Slavic world found itself separated and protected from Europe’s deadening rationalism, the external and formal character of Europe’s juridical law (inherited from Rome), and the coercive character of European governmental power, which was formed as a result of military conquests; moreover, in these circumstances, the Church in Russia had preserved its “purity,” remaining independent of the governmental authority and secular goals.

Eastern Christianity, leading (as Kireevskii believed) from discursive rationalistic thinking to a free moral intuitive understanding, was assimilated by Russia in a form undistorted by the classical heritage. According to Kireevskii, the purity and undistorted character of its Christian principles are what give Russian culture a right to claim that it has a special role to play in the history of humankind. The “seed” (which is how he figuratively referred to the religious idea) has fallen onto a special “soil”—the Slavic national soul, which is characterized

“both by dignity and by humility, attesting to equilibrium of spirit” (Kireevskii 1984, p. 224). But the main thing is that the Slavic “soil” is characterized by an original native principle of the organization of social life—the *obshchina* (or Russian commune). Not the personal right to property (as in the West) but the communal ownership of land is the foundation of the “relations of social life” in Russian society, for which individualism is a foreign principle. This is precisely why Kireevskii believed that the “new” philosophy and culture, so indispensable for humankind, could arise in his country. He associated the birth of this new thinking not with the construction of systems but with a radical transformation of the social consciousness, with the “education of society” as a result of common efforts rooted in *sobornost*. In this way, society will experience the infusion of a new philosophy that will overcome rationalism. This new philosophy will reorient humankind’s spiritual life and produce in both society and in the individual an inner integrity of consciousness, a harmony of the social life.

By no means did this opposition between the Western fragmentedness and individualism and the Russian integrity and *sobornost* lead Kireevskii to reject the Western tradition. He dreamt of “integrity”; and here his ideal was the synthesis of what he considered the best features of the spiritual life of the West and of the East in such a manner that the “Russian principles,” without nullifying European culture, would bestow upon the latter “higher meaning and definitive development” (Kireevskii 1984, p. 238). In the light of this, for Kireevskii the task of an original Russian philosophy would be the reworking of contemporary Western philosophy in the spirit of the teachings of Eastern patristics.

Kireevskii’s views influenced a number of twentieth-century Russian philosophers, including Nikolai Berdiaev, Sergei Bulgakov, and Dmitrii Merezhkovskii. Kireevskii’s central ideas—for example, about Orthodoxy as the foundation of Russian culture; the “conciliar” (*soborny*) nature of knowledge; and the fundamental difference between the European and Russian cultural traditions—have had a great impact and become the subject of close study by philosophers both in Russia and in Europe and North America.

## KITCHER, PATRICIA

(1948–)

Patricia Kitcher is widely known for her work on Kant and on philosophy of psychology. Born Patricia Williams, she attended Wellesley College and then graduate school in philosophy at Princeton where she studied with George Pitcher. Kitcher's interest in cognition manifested early and has continued to shape and inform her work throughout her career. Her doctoral dissertation defended a psychological continuity criterion for personal identity but extended the scope of the psychological criterion beyond that traditionally posited to include broader and more abstract cognitive characteristics, such as cognitive approach or cognitive style. Since then her work has ranged widely from traditional philosophy of psychology, to Freud, and ultimately to her greatest philosophical passion: Kant scholarship.

In her early work Kitcher wrote a number of papers in philosophy of psychology, philosophy of mind, and philosophy of science. She argued for the viability of intentional psychology and the autonomy of functionalist psychology from neurophysiology. Later work predominantly concentrated on analysis of problems stemming from the interpretation of Kant's first *Critique*.

Kitcher has written numerous articles on the forms of intuition, Kant's epistemology, self-consciousness, and on how transcendental arguments work.

Kitcher has written two books that also pursue psychological themes. *Kant's Transcendental Psychology* was a radical departure from most Kant exegesis. The book makes two main claims about the *Critique of Pure Reason*. First, contra Peter Frederick Strawson, Kitcher argues that to understand synthetic a priori knowledge, it is essential to consider transcendental psychology. Second, she explicates a Kantian argument for the necessity of an integrated thinking subject, which serves as a reply to David Hume's denial of the unity of the self. An expanded and amended version of this position is being fleshed out more fully in a book she is currently writing, *Kant's Thinker*, which also explores the question of how we are to understand the faculties, and how the *Critique* contributes to debates about conscious and unconscious ideas.

In *Freud's Dream* Kitcher argued that Freud was the first cognitive scientist: Psychoanalysis should be thought of as an exercise in interdisciplinary theory construction, and as such, it illuminates the pitfalls to which such interdisciplinary approaches are subject. (Kitcher jokes that her arguments managed to alienate all readers: Freudians, because she exposes the mistaken foundation of psychoanalysis, and anti-Freudians, because she portrays his program as scientifically legitimate.)

Around the turn of the new century, Kitcher's interests turned toward Kantian ethics. Her works from this period provide an account of Kantian *maxims* and an interpretation of Kant's argument for the Formulation of the Universal Law for the Categorical Imperative, a task that has led many other Kant experts to throw up their hands in perplexity.

Kitcher's prodigious published contributions to philosophy are matched by her contributions to the philosophical community. She has served as department chair in three different universities, on numerous academic committees (including being a founding chair of the UC committee on the status of women), as president of the Society for Philosophy and Psychology, as president of the North American Kant Society, and on the editorial board of *Journal of Philosophy*. Her philosophical integrity, her fiery lectures, and her incisive comments on student papers make her an inspiring teacher and mentor.

Patricia Kitcher has held faculty positions at the University of Vermont, the University of Minnesota, and University of California, San Diego, and a visiting position at

University of Michigan. In 1998 she went to Columbia University where she became the Mark van Doren Professor of the Humanities and chair of the philosophy department. She lives in New York City with her husband, Philip, also a philosopher, with whom she has two sons, Andrew and Charles.

## KLAGES, LUDWIG

(1872–1956)

Ludwig Klages, a German psychologist and philosopher, was the leading figure in the field of characterology. Born in Hanover, Klages studied chemistry, physics, and philosophy at Munich, receiving his doctorate in chemistry in 1900. As a member of the Stefan George circle, he collaborated with George in the editing of the *Blättern für die Kunst*. In 1905 Klages founded at the University of Munich a *Seminar für Ausdruckskunde*, which soon became Germany’s main center of characterological psychology. In 1919 the seminar was moved to Kilchberg, near Zürich, where Klages remained until his death.

Klages was the principal representative in psychology of the vitalist movement that swept Germany from 1895 to 1915. His most important work was directed toward the formulation of a science of character that would reestablish the undifferentiated union of the life forms that had been ruptured by the emergence of ego in the human species. To this end he explored some of the more bizarre pseudo sciences, such as graphology, and attempted to use their insights as the bases for auxiliary disciplines in his study of character types.

In addition to the literary influences of the romantic poets, of Johann Wolfgang von Goethe, and of Stefan George, Klages was also influenced by the physiologist E. G. Carus and the psychologist Theodore Lipps and, most important, by the philosopher Friedrich Nietzsche. All of these strands of thought converged in Klages to make of him a major spokesman of a generation of intellectuals consciously dedicated to the repudiation of reason in the name of instinct, and of civilization in the name of life. In short, his work was similar in content and general effect to that of Ernst Jünger, Oswald Spengler, and Martin Heidegger in providing—however unintentionally—an intellectual basis for Nazism.

According to Klages, Nietzsche had perceived correctly that man was distinguished from the rest of animal nature only by his ability to clothe in images the reality given by the senses. But Nietzsche had been wrong, Klages maintained, to regard this image-making ability as necessarily acting in the service of vital forces. In fact, he argued, man’s ability to conceive a world in the imagination and to present this imagined world as a project or possible attainment against lived experience was unnatural and, in the end, profoundly hostile to life itself. Human life, for Klages, differed from animal life in general by virtue of the emergence in man of spirit (*Geist*); man’s capacity to think and to will provided the source of his estrangement from the world and the cause of his peculiar psychic illnesses.

Animal life is possessed of both body (*Leib*) and soul (*Seele*), whose functions constitute “genuine processes.” “The Body finds expression in the process of sensation and in the impulse towards movement, the Soul in the process of contemplation and in the impulse to formation (that is, to the magical *or* mechanical realization of images) ... .” The processes of body and soul express the “eternal” life force, which is characterized by spontaneous creativity and flows beneath individual duration. In man, however, spirit appears, characterized by the “act of apprehension and the act of willing,” which are in turn the origin of ego, utterly lacking in animals and impelling

man to the “unnatural” desire for immortality “or, more briefly, the urge to self-preservation.”

This unnatural urge to self-preservation in man creates the tensions of human life. Man is a field whereon animal consciousness and human consciousness vie for supremacy. The former promotes the impulse to return to nature, expressed in the quest for “eternal life,” while the latter promotes the life-destructive impulse to transcend the animal condition, reflected in science, religion, philosophy, and even art. The different quanta of soul and spirit present within an individual account for differences in character. Characterology, which is the study of these differences, constructs a typology of attitudes and structural forms as manifested in different egos. Most men live in the middle range of a spectrum of characterological types that runs from an almost total repression of spirit, as in primitive peoples, to an almost total repression of bodily forces, as in the asceticism of the redemptive religions. But in the science of character, Klages hoped, the true nature of the struggle between life and spirit raging in the individual would be clarified, the disastrous consequences of the triumph of spirit over life would be revealed, and science, art, and religion would be turned upon the spirit, destroy it, and lead to the dissolution of the individual ego in the undifferentiated nature out of which it had unnaturally emerged.

## KLEIST, HEINRICH VON

(1777–1811)

Heinrich von Kleist, a German dramatist, poet, and novelist, was born in Frankfurt on the Oder. Following a family tradition, Kleist entered the Prussian military service at fourteen, but he left, dissatisfied, in 1799. Uncertain what profession to adopt, Kleist prepared himself for the university by studying privately philosophy, mathematics, and classical languages. An intensive study of Immanuel Kant, or perhaps of Johann Gottlieb Fichte, led to a spiritual crisis in March 1801. The relativity of all knowledge seemed to Kleist to render life, especially a life dedicated to the pursuit of knowledge, pointless. In disgust he discontinued his studies and journeyed to Paris and Switzerland. His decision to pursue a literary career led to a second crisis: Afraid that he had no talent, he burned his tragedy *Robert Guiskard* in 1803. A period of restless activity followed. In 1805 he obtained a minor civil service position in Königsberg, which relieved him of his immediate worries. His two comedies, *Amphitryon* and *Der zerbrochene Krug*, were written at this time. Eager to aid the anti-Napoleonic cause he left Königsberg for Berlin, where in 1807 he was seized as a spy and sent to prison in France. After his sister had obtained his release, Kleist made an attempt to establish himself in Dresden from 1807 to 1809. With Adam Müller he founded the literary magazine *Phöbus*, which, however, soon failed. Attempts to help the patriotic cause with his literary efforts (*Hermannsschlacht*, 1808) met with little response. He returned to Berlin, where for a time he published the *Abendblätter*. When this project also failed, partly because of political pressure, Kleist was left without means. On November 21, 1811, Kleist committed suicide with Henriette Vogel near Berlin.

Kleist's reading of Kant taught him that all attempts to penetrate the veil of phenomena were futile, that the world possesses no higher meaning. In his first play, *Die Familie Schroffenstein* (1803), love, the only value, is destroyed by the force of illusion and circumstance—a theme that was to recur in such stories as *Die Verlobung in St. Domingo* and *Das Erdbeben in Chile*. Like G. W. F. Hegel, Kleist saw life as essentially tragic, but unlike Hegel, he saw tragedy in absurdity, in the indifference of the world to man's demands for love and meaning.

Kleist's heroes confront this absurdity with demonic defiance. Thus Michael Kohlhaas, in the novella of the same name (1810), becomes inhuman in his pursuit of justice; and the heroines of Kleist's plays *Penthesilea* (1808) and *Das Käthchen von Heilbronn* (1810) become inhuman in their pursuit of love—one by being totally aggressive, the other by being totally submissive. In his last play, *Der Prinz von Homburg* (1810), Kleist attempted to oppose the order provided by the state to the uncertainties of the human situation. The prince disobeys orders, wins a battle, and yet is condemned to death. At first incapable of understanding this judgment and driven only by his fear of death, he regains control of himself when made judge of his own actions, and freely accepts the verdict.

## KNOWLEDGE, A PRIORI

The prominence of the a priori within traditional epistemology is largely due to the influence of Immanuel Kant's *Critique of Pure Reason* (1781), where he introduces a conceptual framework that involves three distinctions: the epistemic distinction between a priori and empirical (or a posteriori) knowledge; the metaphysical distinction between necessary and contingent propositions; and the semantic distinction between analytic and synthetic propositions. Within this framework, Kant poses four questions:

1. What is a priori knowledge?
2. Is there a priori knowledge?
3. What is the relationship between the a priori and the necessary?
4. Is there synthetic a priori knowledge?

These questions remain at the center of the contemporary debate.

Kant maintains that a priori knowledge is "independent of experience," contrasting it with a posteriori knowledge, which has its "sources" in experience (1781, p. 43). He offers two criteria for a priori knowledge, necessity and strict universality, which he claims are inseparable from one another. Invoking the first, he argues that mathematical knowledge is a priori. Kant's claim that necessity is a criterion of the a priori entails:

(K1) All knowledge of necessary propositions is a priori.

He also appears to endorse

(K2) All propositions known a priori are necessary.

Kant maintains that all propositions of the form "All A are B" are either analytic or synthetic: analytic if the predicate is contained in the subject; synthetic if it is not. Utilizing this distinction, he argues that

(K3) All knowledge of analytic propositions is a priori; and

(K4) Some propositions known a priori are synthetic.

In support of (K4), Kant claims that the predicate terms of "7 + 5 = 12" and "The straight line between two points is the shortest" are not contained in their respective subjects.

## THE CONCEPT

Kant provides the core of the traditional conception of the a priori. When he speaks of the source of knowledge, he does not mean the source of the belief in question, but the source of its justification. Hence, according to Kant,

(APK) S knows a priori that p if and only if S's belief that p is justified a priori and the other conditions on knowledge are satisfied; and

(APJ) S's belief that p is justified a priori if and only if S's justification for the belief that p does not depend on experience.

(APJ) has been criticized from two directions. First, some maintain that it is not sufficiently informative; it tells one what a priori justification is not, but not what it is. Hence, Laurence Bonjour (1985) rejects (APJ) in favor of

(AP1) S's belief that p is justified a priori just in case S intuitively "sees" or apprehends that p is necessarily true.

Alvin Plantinga (1993) and Bonjour (1998) offer variants of (AP1). Second, others maintain that the sense of *dependence* relevant to a priori justification requires articulation and offer two competing accounts. Albert Casullo (2003) endorses

(AP2) S's belief that p is justified a priori if and only if S's belief that p is nonexperientially justified (i.e., justified by some nonexperiential source).

Hilary Putnam (1983) and Philip Kitcher (1983) favor

(AP3) S's belief that p is justified a priori if and only if S's belief that p is nonexperientially justified and cannot be defeated by experience.

(AP1) and (AP3) face serious objections.

The term *see* is used metaphorically in (AP1). Let us assume that it shares with the literal use of *see* one basic feature: "S sees that p" entails "S believes that p." Hence, (AP1) has the consequence that if S's belief that p is justified a priori then S believes that p is necessarily true. This consequence faces two problems. Suppose that Sam is a mathematician who believes some generally accepted theorem T on the basis of a valid proof. Presumably, Sam's belief is justified. But suppose that Sam is also a serious student of philosophy who has come to doubt the cogency of the distinction between necessary and contingent propositions and, as a consequence, refrains from modal beliefs. It is implausible to maintain that Sam's belief that T is not justified a priori merely because of his

views about a controversial metaphysical thesis. (AP1) is also threatened with a regress. It entails that if S's belief that p is justified a priori then S believes that necessarily p. Must S's belief that necessarily p be justified? If not, it is hard to see why it is a necessary condition of having an a priori justified belief that p. If so, then presumably it is justified a priori. But for S's belief that necessarily p to be justified a priori, S must believe that necessarily necessarily p, and the same question arises with respect to the latter belief. Must it be justified or not? Hence, (AP1) must either maintain that having an unjustified belief that necessarily p is a necessary condition of having a justified belief that p, or face an infinite regress of justified modal beliefs.

(AP3) is also open to serious objection. Saul Kripke (1980) and Kitcher (1983) maintain that an adequate conception of a priori knowledge should allow for the possibility that a person knows empirically some proposition that he or she can know a priori. (AP3) precludes this possibility. Assume that

(A) S knows empirically that p and S can know a priori that p.

From the left conjunct of (A), it follows that

(1) S's belief that p is justified<sub>k</sub> empirically,

where "justified<sub>k</sub>" abbreviates "justified to the degree minimally sufficient for knowledge." Consider now the empirical sources that have been alleged to justify mathematical propositions empirically: counting objects, reading a textbook, consulting a mathematician, and computer results. (Tyler Burge [1993] discusses the relationship between testimony and a priori knowledge.) Each of these sources is fallible in an important respect. The justification each confers on a belief that p is defeasible by an empirically justified overriding defeater; that is, by an empirically justified belief that not-p. If S's belief that p is justified by counting a collection of objects and arriving at a particular result, then it is possible that S recounts the collection and arrives at a different result. If S's belief that p is justified by a textbook (or mathematician or computer result) that states that p, then it is possible that S encounters a different textbook (or mathematician or computer result) that states that not-p. In each case, the latter result is an empirically justified overriding defeater for S's original justification. Hence, given the fallible character of empirical justification, it follows that

(2) S's empirical justification for the belief that p is defeasible by an empirically justified belief that not-p.

(2), however, entails that

- (3) S's belief that not-p is justifiable<sub>d</sub> empirically,

where "justifiable<sub>d</sub>" abbreviates "justifiable to the degree minimally sufficient to defeat S's justified<sub>k</sub> belief that p." Furthermore, the conjunction of (AP3) and the right conjunct of (A) entails

- (4) It is not the case that S's nonexperiential justification<sub>k</sub> for the belief that p is defeasible by S's empirically justified belief that not-p.

(4), however, entails that

- (5) It is not the case that S's belief that not-p is justifiable<sub>d</sub> empirically.

The conjunction of (3) and (5) is a contradiction. Hence, (AP3) is incompatible with (A). (AP2), however, is compatible with (A) since the conjunction of (AP2) and the right conjunct of (A) does not entail (4).

## SUPPORTING ARGUMENTS

Kant offers the most influential traditional argument for the existence of a priori knowledge. He holds that necessity is a criterion of the a priori: "[I]f we have a proposition which in being thought is thought as *necessary*, it is an a priori judgment" (1965, p. 43). He then argues that "mathematical propositions, strictly so called, are always judgments a priori, not empirical; because they carry with them necessity, which cannot be derived from experience" (p. 52). Kant's argument can be presented as follows:

- (K1) All knowledge of necessary propositions is a priori.  
 (K2) Mathematical propositions are necessary.  
 (K3) Therefore, knowledge of mathematical propositions is a priori.

Premise (K1) is ambiguous. There are two ways of reading it:

- (K1T) All knowledge of the truth value of necessary propositions is a priori; or  
 (K1G) All knowledge of the general modal status of necessary propositions is a priori.

Kant supports (K1) with the observation that "[e]xperience teaches us that a thing is so and so, but not that it cannot be otherwise" (1965, p. 52). This observation supports (K1G) but not (K1T), since Kant allows that experience can provide evidence that something is the case, but denies that it can provide evidence that something

must be the case. The conclusion of the argument, however, is that knowledge of the truth value of mathematical propositions, such as that  $7 + 5 = 12$ , is a priori.

Kant's argument can now be articulated as follows:

- (K1G) All knowledge of the general modal status of necessary propositions is a priori.  
 (K2) Mathematical propositions are necessary.  
 (K3T) Therefore, knowledge of the truth value of mathematical propositions is a priori.

The argument involves this assumption:

- (KA) If the general modal status of p is knowable only a priori, then the truth value of p is knowable only a priori.

(KA), however, is false. If one can know only a priori that a proposition is necessary, then one can know only a priori that a proposition is contingent. The evidence relevant to determining the latter is the same as that relevant to determining the former. For example, if I determine that " $2 + 2 = 4$ " is necessary by trying to conceive of its falsehood and failing, I determine that "Kant is a philosopher" is contingent by trying to conceive of its falsehood and succeeding. However, if my knowledge that "Kant is a philosopher" is contingent is a priori, it does not follow that my knowledge that "Kant is a philosopher" is true is a priori. Clearly, it is a posteriori.

Roderick Chisholm (1977) suggests the following reformulation of Kant's argument:

- (K1G) All knowledge of the general modal status of necessary propositions is a priori.  
 (K2) Mathematical propositions are necessary.  
 (K3G) Therefore, knowledge of the general modal status of mathematical propositions is a priori.

This argument faces a different problem. Why accept Kant's claim that experience can teach one only what is the case? A good deal of one's ordinary practical knowledge and the bulk of one's scientific knowledge provide clear counterexamples to the claim. My knowledge that my pen will fall if I drop it does not provide information about what is the case for the antecedent is contrary to fact. Scientific laws are not mere descriptions of the actual world. They support counterfactual conditionals and, hence, provide information beyond what is true of the actual world. In the absence of further support, Kant's claim should be rejected.

A second strategy for defending the existence of a priori knowledge is offered by proponents of logical empiricism, such as Alfred Jules Ayer (1952) and Carl Hempel (1972), who reject John Stuart Mill's contention that knowledge of basic mathematical propositions, such as that  $2 \times 5 = 10$ , is based on induction from observed cases. Both draw attention to the fact that if one is justified in believing that some general proposition is true on the basis of experience, then contrary experiences should justify one in believing that the proposition is false. But no experiences would justify one in believing that a mathematical proposition, such as that  $2 \times 5 = 10$ , is false. Suppose, for example, that I count what appear to be five pairs of shoes and arrive at the result that there are only nine shoes. Ayer contends that

[o]ne would say that I was wrong in supposing that there were five pairs of objects to start with, or that one of the objects had been taken away while I was counting, or that two of them had coalesced, or that I had counted wrongly. One would adopt as an explanation whatever empirical hypothesis fitted in best with the accredited facts. The one explanation which would in no circumstances be adopted is that ten is not always the product of two and five. (1952, pp. 75–76)

Since Ayer maintains that one would not regard any experiences as evidence that a mathematical proposition is false, he concludes that no experiences provide evidence that they are true.

Ayer's argument can be stated as follows:

- (A1) No experiences provide evidence that mathematical propositions are false.
- (A2) If no experiences provide evidence that mathematical propositions are false, then no experiences provide evidence that they are true.
- (A3) Therefore, no experiences provide evidence that mathematical propositions are true.

Ayer's defense of (A1) is weak in several respects. First, it does not take into account the number of apparent confirming instances of the proposition in question. Second, it involves only a single disconfirming instance of the proposition. Third, the hypotheses that are invoked to explain away the apparent disconfirming instance are not subjected to an independent empirical test. In a situation where there is a strong background of supporting evidence for an inductive generalization and an isolated disconfirming instance, it is reasonable to discount the

disconfirming instance as apparent and to explain it away on whatever empirical grounds are most plausible.

The case against premise (A1) can be considerably strengthened by revising Ayer's scenario as follows: Increase the number of disconfirming instances of the proposition so that it is large relative to the number of confirming instances; and subject the hypotheses invoked to explain away the apparent disconfirming instances to independent tests that fail to support them. Let us now suppose that one has experienced a large number of apparent disconfirming instances of the proposition that  $2 \times 5 = 10$  and, furthermore, that empirical investigations of the hypotheses invoked to explain away these disconfirming instances produce little, if any, support for the hypotheses. Given these revisions, Ayer can continue to endorse premise (A1) only at the expense of holding empirical beliefs that are at odds with the available evidence.

## OPPOSING ARGUMENTS

Radical empiricism is the view that denies the existence of a priori knowledge. Its most famous proponents are John Stuart Mill and Willard Van Orman Quine. One common strategy that radical empiricists employ in arguing against the existence of a priori knowledge is to consider the most prominent examples of propositions alleged to be knowable only a priori and to maintain that such propositions are known empirically. Since mathematical knowledge has received the most attention, this entry will focus on it.

Mill's (1973) account of mathematical knowledge is a version of inductive empiricism. Inductive empiricism with respect to a domain of knowledge involves two theses. First, some propositions within that domain are epistemically more basic than the others, in the sense that the nonbasic propositions derive their justification from the basic propositions via inference. Second, the basic propositions are known by a process of inductive inference from observed cases. Mill's focus is on the basic propositions of arithmetic and geometry, the axioms and definitions of each domain. His primary thesis is that they are known by induction from observed cases.

Mill's position faces formidable objections, such as those offered by Gottlob Frege (1974). Let us assume, however, that these objections can be deflected and that Mill offers a plausible inductive empiricist account of mathematical knowledge to assess how this concession bears on the existence of a priori knowledge. If Mill is right, then all epistemically basic propositions of arithmetic and geometry are justified on the basis of observa-

tion and inductive generalization. It follows that Kant's claim that mathematical knowledge cannot be derived from experience is wrong. It does not follow, however, that the claim that such knowledge is a priori is wrong. From the fact that mathematical knowledge is or can be derived from experience, it does not immediately follow that such knowledge is not or cannot be derived from some nonexperiential source. Mill is aware of the gap in his argument and attempts to close it with the following observations:

They cannot, however, but allow that the truth of the axiom, Two straight lines cannot inclose a space, even if evident independently of experience, is also evident from experience. ... Where then is the necessity for assuming that our recognition of these truths has a different origin from the rest of our knowledge, when its existence is perfectly accounted for by supposing its origin to be the same? ... The burden of proof lies on the advocates of the contrary opinion: it is for them to point out some fact, inconsistent with the supposition that this part of our knowledge of nature is derived from the same sources as every other part. (1973, pp. 231–232)

Mill moves from the premise that inductive empiricism provides an account of knowledge of mathematical axioms to the stronger conclusion that knowledge of such axioms is not a priori by appealing to a version of the explanatory simplicity principle: If a putative source of knowledge is not necessary to explain knowledge of the propositions within some domain, then it is not a source of knowledge of the propositions within that domain. Mill's argument can be articulated as follows:

- (M1) Inductive empiricism provides an account of mathematical knowledge based on inductive generalization from observed cases.
- (M2)  $\phi$  is a source of knowledge for some domain D only if  $\phi$  is necessary to explain knowledge of some propositions within D.
- (M3) Therefore, mathematical knowledge is not a priori.

The burden of the argument is carried by (M2), the explanatory simplicity principle.

Casullo (forthcoming) maintains that the explanatory simplicity principle conflicts with a familiar fact of one's epistemic life. The justification of some of one's beliefs is overdetermined by different sources. There are some beliefs for which one has more than one justifica-

tion, each of those justifications derives from a different source, and each, in the absence of the others, is sufficient to justify the belief in question. For example, I have misplaced my wallet again and wonder where I might have left it. I suddenly recall having left it on the kitchen table when I came in from the garage last night. My recollection justifies my belief that my wallet is on the kitchen table. However, just to be sure, I walk out to the kitchen to check. To my relief, I see my wallet on the table. My seeing my wallet on the table also justifies my belief that my wallet is on the table. So here my justification is overdetermined by different sources. If the justification of my belief is overdetermined by two different sources, it follows that my belief is justified by two different sources. Hence, in the absence of an argument against the possibility of epistemic overdetermination, Mill's appeal to the explanatory simplicity principle simply begs the question.

Quine rejects inductive empiricism. He rejects the idea that there are basic mathematical propositions that, taken in isolation, are directly justified by observation and inductive generalization. Quine's account of mathematical knowledge is a version of holistic empiricism. Mathematical propositions are components of scientific theories. They are not tested directly against observation, but only indirectly via their observational consequences. Moreover, they do not have observational consequences in isolation, but only in conjunction with the other propositions of the theory. Hence, according to holistic empiricism, entire scientific theories, including their mathematical components, are indirectly confirmed or disconfirmed by experience via their observational consequences.

The main concern in this entry is not to assess the cogency of Quine's account of mathematical knowledge, but to determine whether it provides an argument against the existence of a priori knowledge. The argument of Quine's classic paper "Two Dogmas of Empiricism" (1963) remains controversial (for further discussion, see Boghossian 1996). The stated target of his attack is a conception of analyticity inspired by Frege: A statement is analytic if it can be turned into a logical truth by replacing synonyms with synonyms. Quine's contentions can be summarized as follows:

- (1) Definition presupposes synonymy rather than explaining it.
- (2) Interchangeability *salva veritate* is not a sufficient condition of cognitive synonymy in an extensional language.

- (3) Semantic rules do not explain “Statement S is analytic for language L,” with variable “S” and “L.”
- (4) The verification theory of meaning provides an account of statement synonymy that presupposes reductionism, but reductionism fails.
- (5) Any statement can be held to be true come what may. No statement is immune to revision.

Quine’s contentions appear to be directed at the concept of synonymy and the doctrine of reductionism. They are not explicitly directed at a priori knowledge. Hence, if “Two Dogmas” does indeed present a challenge to the existence of a priori knowledge, then some additional premise is necessary that connects those contentions to the a priori.

According to the traditional reading of his argument, Quine’s contentions constitute an extended attack on the cogency of the analytic-synthetic distinction. Quine’s ultimate goal is to undermine the central claim of the logical empiricist tradition:

(LE) All a priori knowledge is of analytic truths.

On this reading, (LE) provides the connection between his contentions and the rejection of the a priori. Let us grant that Quine’s goal is to undermine (LE) and that he successfully challenges the cogency of the analytic-synthetic distinction. Does it follow that there is no a priori knowledge? No. (LE) is a thesis about the nature of the propositions alleged to be known a priori. If Quine is right, then (LE) itself is incoherent. But from the fact that a thesis about the nature of propositions known a priori is incoherent, it does not follow that there is no a priori knowledge.

An alternative response is to take (LE) as a conceptual claim; that is, to take it as claiming that the concept of a priori knowledge involves the concept of analytic truth. On this reading, the incoherence of the concept of analytic truth entails the incoherence of the concept of a priori knowledge. This response, however, rests on a false conceptual claim. The concept of a priori knowledge does not explicitly involve the concept of analytic truth. One might argue that it implicitly involves the concept of analytic truth by maintaining that all a priori knowledge is of necessary truths; and endorsing some version of the so-called linguistic theory of necessary truth. There are, however, two problems with this argument. First, the concept of a priori knowledge does not involve, either explicitly or implicitly, the concept of necessary truth.

Second, there is no plausible analysis of the concept of necessary truth in terms of the concept of analytic truth.

Some champions of “Two Dogmas” propose an alternative connection between Quine’s contentions and the rejection of the a priori. Putnam (1983) maintains that Quine’s contentions are directed toward two different targets. The initial contentions are directed toward the semantic concept of analyticity. Contention (5), however, is directed toward the concept of a statement that is confirmed no matter what, which is not a semantic concept. The concept of a statement that is confirmed no matter what is an epistemic concept. It is a concept of apriority. Kitcher endorses Putnam’s reading of Quine’s argument, “If we can know a priori that *p* then no experience could deprive us of our warrant to believe that *p*” (1983, p. 80). But, according to Quine, no statement is immune from revision. Hence, the Putnam-Kitcher version of Quine’s argument can be stated as follows:

- (Q1) No statement is immune to revision in light of recalcitrant experience.
- (Q2) If S’s belief that *p* is justified a priori, then S’s belief that *p* is not rationally revisable in light of any experiential evidence.
- (Q3) Therefore, no knowledge is a priori.

The argument fails. Premise (Q2) is open to the objection presented against (AP3) in the first section.

## THE EXPLANATORY CHALLENGE

A more recent challenge to the a priori derives from Quine’s influential “Epistemology Naturalized” (1969). Epistemic naturalism comes in many different forms. The most radical form advocates the replacement of philosophical investigations into the nature of human knowledge with scientific investigations. More moderate forms advocate that philosophical theories concerning human knowledge cohere with scientific theories. Paul Benacerraf (1973), for example, argues that the truth conditions for mathematical statements make reference to abstract entities and that knowing a statement requires that one be causally related to the entities referred to by its truth conditions. Since abstract entities cannot stand in causal relations, one cannot know mathematical statements. The argument raises a more general challenge to the possibility of a priori knowledge since proponents of the a priori (apriorists) generally hold that most, if not all, a priori knowledge, is of necessary truths; and that the truth conditions of necessary truths make reference to abstract entities. Although some reject the argument on

the grounds that its epistemic premise appears to presuppose the generally rejected causal theory of knowledge, others, such as Hartry Field (1989), maintain that it points to a deeper problem. In the absence of an explanation of how it is possible to have knowledge of abstract entities, a priori knowledge remains mysterious.

The explanatory challenge goes beyond a commitment to epistemic naturalism. It derives support from broader epistemological considerations. To appreciate the full import of the challenge, two issues regarding the existence of a priori knowledge must be distinguished. Apriorists typically maintain that one knows certain logical, mathematical, and conceptual truths and that such knowledge is a priori. Radical skeptics deny that one has knowledge of the truths in question. Radical empiricists, however, are not radical skeptics. They do not deny that one knows the truths in question. Radical empiricists only deny that one's knowledge of these truths is a priori. Therefore, the primary dispute between apriorists and radical empiricists is over the source of the knowledge in question. They offer two competing theories of the source of the knowledge in question, and each maintains that its theory offers the better explanation of the knowledge in question. Therefore, to support their primary contention, apriorists must provide supporting evidence for the claim that there exist nonexperiential sources of justification and that such sources explain how one knows the truths in question.

BonJour (1998) and Ernest Sosa (2000) offer philosophical supporting evidence, a mix of phenomenological and a priori considerations. Casullo (2003) argues that a more promising approach is to supplement the philosophical evidence with evidence based on empirical investigations. Before empirical evidence can be enlisted to support the case for the a priori, however, additional philosophical work is necessary. The first step is to provide (1) a generally accepted phenomenological description of the cognitive states that noninferentially justify beliefs a priori, (2) the type of beliefs they justify, and (3) the conditions under which they justify the beliefs in question. Apriorists typically defend the claim that there are nonexperiential sources of justification by reflecting on their own cognitive situations and identifying phenomenologically distinct states, which they claim justify certain beliefs a priori. A cursory survey of the descriptions of these states offered by different theorists reveals wide variation. George Bealer (1996) and Sosa (1996) both maintain that the cognitive states that justify a priori are aptly described as *seemings*, but they offer different phenomenological descriptions of seemings. Plantinga

(1993) and BonJour (1998) maintain that the states in question are more aptly described as *seeings*, but they offer different phenomenological descriptions of seeings. Bealer agrees with BonJour that the cognitive states that justify a priori are irreducible, but disagrees with him over the character of the states. On the contrary, Sosa agrees with Plantinga that the states are reducible to more familiar cognitive states, but disagrees with him over the character of the reducing states.

There is also wide variation among apriorists over the scope of beliefs justified a priori. Within the context of arguing against radical empiricism, the focus is on stock examples such as elementary logical or mathematical propositions and some familiar examples of alleged synthetic a priori truths. Few apriorists, however, believe that a priori justification is limited to those cases. Consequently, they must provide a more complete specification of the range of beliefs alleged to be justified by such cognitive states. One issue requires particular attention. The examples of a priori knowledge typically cited by apriorists are necessary truths. But here it is important to distinguish between knowledge of the truth value and knowledge of the general modal status of necessary propositions. A critical question now emerges: What is the target of a priori justification? Is it the general modal status of a proposition, its truth value, or both? If it is both, two further questions arise. Are beliefs about the truth value of a necessary proposition and beliefs about its general modal status justified by the same cognitive state or different cognitive states? Are some beliefs about the truth value of contingent propositions justified a priori?

Once the philosophical work is complete, the project of providing empirical supporting evidence for the a priori can be pursued. This involves providing (1) evidence that the cognitive states identified at the phenomenological level are associated with processes of a single type or relevantly similar types; (2) evidence that the associated processes play a role in producing or sustaining the beliefs they are alleged to justify; (3) evidence that the associated processes are truth-conducive; and (4) an explanation of how the associated processes produce the beliefs they are alleged to justify. The third area of empirical investigation offers the prospect of supporting the claim that there are nonexperiential sources of justification. Many prominent apriorists, including Bealer, BonJour, Plantinga, and Sosa, maintain that truth conduciveness is a necessary condition for epistemic justification. Moreover, even those who deny this concede that evidence that a source of beliefs is error conducive defeats whatever justification that the

source confers on the beliefs that it justifies. The claim that a source of beliefs is truth conducive or, more minimally, that it is not error conducive is a contingent empirical claim that can be supported only by empirical investigation.

The fourth area of empirical investigation offers the prospect of addressing the explanatory challenge. First, causal-perceptual models appear to be of limited utility in explaining how nonexperiential sources of justification provide cognitive access to necessary truths. Empirical investigation into human cognition offers the prospect of uncovering alternative models of cognitive access that can be utilized in the case of nonexperiential sources. Second, investigation of the specific cognitive processes associated with the cognitive states alleged to justify a priori may provide a better understanding of how the processes in question produce true beliefs about their subject matter. This understanding, in turn, is the key to providing a noncausal explanation of how the states in question provide cognitive access to the subject matter of the beliefs they produce. Third, although apriorists deny that epistemology is a chapter of science, they acknowledge that both epistemology and science contribute to the overall understanding of human knowledge. Establishing that the cognitive processes invoked by their epistemological theory are underwritten by their scientific commitments strengthens the apriorist's overall theory by demonstrating the coherence of its components.

## KNOWLEDGE, THE PRIORITY OF

One fairly specific understanding of the priority of knowledge is the idea that instead of trying to explain knowledge in terms of belief plus truth, justification, and something, we should explain belief in terms of knowledge. This is to reverse the usual explanatory priority of knowledge and belief. This fairly specific idea generalizes in two directions. (1) Perhaps we should explain other notions in terms of knowledge as well. Some possibilities include assertion, justification or evidence, mental content, and intentional action. (2) Perhaps we could explain other relatively internal states like intentions, attempts, and appearances in terms of their more obviously external counterparts: intentional action and perception.

That knowledge is prior to belief has historically been a minority opinion. The idea that a belief, and the mind more generally, is what it is regardless of any actual connection to the external world is still widely accepted. Accepting the priority of knowledge constitutes a rejection of the picture of the mind as a self-contained, inner realm.

## UNDERSTANDING BELIEF

Bernard Williams (1973) tries to explain the impossibility of believing at will in terms of the idea that belief aims at the truth. Suppose you are anxious about tomorrow's weather but have no access to a weather forecast or any other evidence. If you want to reduce your anxiety, then you might, if it was in your power to do so, simply decide to believe that it will be sunny tomorrow. But if you knew that this attempted belief was based not on evidence or any apparent connection to the facts, but on a decision, then it would be hard for you to see your attempted belief as aiming at the truth. It would also be hard for you to see it as a belief. So, perhaps, it could not be a belief.

Let us agree that in this particular case seeing your attempted belief as the result of a decision seriously casts doubt on the possibility of its being a belief. Is this best explained by the idea that belief aims at the truth? Since you have no evidence about the weather, the problem cannot be that you have reason to think the attempted belief will fail to achieve this aim. On the contrary, you have every reason to think it is at least possible that it will achieve this aim. So what keeps you from aiming at it?

If you merely guess that a flipped coin will come up heads, then you probably do not believe that it will. Guesses are not beliefs. But guessing aims at the truth. In guessing you are trying to get it right, and if you succeed, this is as good as a guess can get. When you see your attempted belief as the result of a decision, you may still be hoping, trying, or aiming to get things right. But you know believing is not epistemically justified for you in that instance. Whatever practical reasons you may have for believing that *p*, you have no evidence that *p*. It is seeing your state as unjustified while remaining in it that seriously casts doubt on the possibility of its being a belief. To understand belief, we need a connection between belief and justification, not just between belief and truth.

Suppose that someone has an unjustified, true belief. If belief aims at the truth, then this belief has achieved its aim. Perhaps justification is a good guide or a means to the truth. But if truth is the aim, and this belief has achieved that aim by other means, then epistemic justifi-

cation or lack thereof is irrelevant to the evaluation of this belief. So if belief merely aimed at the truth, then it would not be automatically subject to evaluation from the epistemic point of view. If belief aims at knowledge, however, instead of mere truth, then it is clear why it is subject to this kind of evaluation. Unjustified beliefs may be true, but they cannot constitute knowledge.

Perhaps this does not capture what is meant in saying that belief aims at the truth. When you believe that *p*, you do not merely hope or try to get things right. In some sense it seems to you as though you already have gotten things right. We do not want to say that if you believe that *p*, you believe that your belief that *p* is true. This leads to an infinite number of beliefs. You do not need beliefs about beliefs to have beliefs about the world. But if you do have a view about your views, it must cohere with those views, where coherence involves more than just logical consistency. You can think that your belief that *p* is true, but you cannot think that your belief that *p* is false. You cannot assert, "I believe that *p*, but not *p*," and you cannot believe it either. This "cannot" is probably a normative "cannot," rather than an expression of logical impossibility.

What goes for error goes for ignorance as well. There is something wrong with assertions of the form "*p*, but I do not believe that *p*." Whatever is wrong with these assertions, they would be just as bad in the privacy of your own mind. If you think about Moore-paradoxical statements from the normative perspective, then the same kind of incoherence that is involved in the standard cases also seems to infect the following: *p*, but I have no reason to believe that *p*; I believe that *p*, but I should not believe it; and *p*, but I am completely unreliable about these things. The belief that *p* not only conflicts with the belief that you are wrong or that you do not believe that *p*. It also rules out the belief that you are unjustified or not in a position to know. These first-person facts about belief can be explained by the idea that belief aims at knowledge, but not by the idea that belief aims at truth.

The idea that belief aims at knowledge is a normative claim. From the point of view of belief there is something wrong with false beliefs, but there is also something wrong with unjustified beliefs. There is something wrong with accidentally true beliefs, even when they are justified. But from the point of view of belief, there is nothing wrong with knowledge. For a belief, knowledge is as good as it gets.

## ASSERTION AND EVIDENCE

Moore's Paradox tells us not only about the nature of belief but also about the nature of assertion. Peter Unger

(1975) and Timothy Williamson (2000) are both defenders of the priority of knowledge. Both agree that when you assert that *p*, you not only represent *p* as being true—you not only represent yourself as believing that *p*—you also represent yourself as knowing that *p*. Propositions of the form “*p*, but I do not know that *p*” are unassertable because they violate the rule of assertion: assert only what you know. Unlike Williamson, Unger is a radical skeptic. When he tells you not to assert what you do not know, he is basically telling you to keep quiet. The consequences you draw from the priority of knowledge will depend on your general views about knowledge. But the basic idea does not discriminate against skeptics.

Unger and Williamson also agree that there is an important connection between knowledge and justification, though they articulate the connection in different ways. Unger’s general idea is that if you are justified in believing that *p*, then you must know something. More specifically, he believes that if your reason for believing that *p* is that *q*, then you must know that *q*. According to Williamson evidence is knowledge. If your body of evidence consists of a set of propositions, then you must know each member of this set. Both of these views open up the possibility of merely apparent evidence. This is not a problem for Unger, since he thinks that all evidence is merely apparent.

Is there a problem for Williamson? Suppose you have a justified, false belief that *p*; you infer that *q* on the basis of this belief; and you think that *p* is your evidence that *q*. If evidence is knowledge, then you are simply mistaken in thinking that *p* is your evidence that *q*. You may even be mistaken in thinking that you have evidence that *q*. This can seem problematic if you think that evidence is such that, if you have some, then you are at least in a position to know that you have some; and if you do not have any, then you are in a position to know that you do not have any; and if *p* is or is not evidence for you to believe that *q*, then you are in a position to know whether or not this is so.

According to Williamson evidence is not this kind of thing, but neither is anything else. In Williamson’s terminology a condition is “luminous” just in case one is in a position to know that the condition obtains, if it does. For example, you could easily be sleeping in a cold room without being able to tell that the room is cold. So the condition of one’s being in a cold room is not luminous. But you might have thought that, if you feel cold, seem to see a red wall, or believe that there is life on Mars, then you are in a position to know that you feel cold, seem to see a red wall, or believe that there is life on Mars. In other

words you might have thought that these conditions are luminous.

Williamson has a general argument designed to show that there are no nontrivial luminous conditions. Not even the condition that one feels cold is luminous. There is always a potential gap between the facts and your ability to know the facts, even when the facts are about your own present state of mind. So the idea that evidence would not be luminous if only knowledge were or could be evidence is no objection to the view. Evidence would not be luminous regardless what it was. If we do have some other form of privileged access to evidence or the justification of our own beliefs, and if our having that access is incompatible with the idea that evidence is knowledge, then it must be shown.

## MENTAL CONTENT

Gilbert Harman (1999) believes that the basic mental notions are knowledge and intentional action. Belief and intention are generalizations of these that allow for error and failure. Harman therefore clearly endorses the priority of knowledge. He also believes that the content of a concept is determined by its functional or conceptual role: its typical or normal connections to perception, its role in practical and theoretical reasoning, and its connection to intentional action. Finally, he accepts content externalism: the view that it is possible for intrinsic duplicates to differ in the contents of their thoughts.

The first two of Harman’s views explain why he holds the third. My concept of water is typically caused by perceptions of and hearing about water, and the concept is causally involved in my intentional interactions with water. Suppose that I have an intrinsic duplicate on Hilary Putnam’s (1975) Twin Earth. On Twin Earth there is something that looks, smells, tastes, and feels like water but is not water. Call it XYZ. When I interact with water, my twin interacts with XYZ. This difference in our interactions does not influence our intrinsic natures. But it does influence the contents of our thoughts. Unlike me, my twin never perceives or interacts with water. Even if you dragged my twin into my kitchen, he would not intentionally interact with water, nor would he perceive that the water was running. My concept differs in content from my duplicate’s concept because the functional roles of the concepts are different. The functional roles of the concepts are different because these roles must be understood in terms of knowledge, perception, and intentional action.

Harman is not the only philosopher to combine the priority of knowledge with a conceptual role account of

content. Christopher Peacocke (1999) has a sophisticated version of this view. According to Peacocke epistemically individuated concepts can be individuated, at least in part, in terms of the conditions under which certain judgments involving those concepts would constitute knowledge. Furthermore, every concept is either epistemically individuated, or individuated in part in terms of its relations to epistemically individuated concepts. If epistemically individuated concepts do in fact play this central role in our system of concepts, then the priority of knowledge may provide an explanation of this fact.

The conceptual role theory of content is or is a descendant of the idea that the content of a thought or concept is determined by what Wilfrid Sellars (1956) calls its place in a space of reasons. John McDowell (1996) argues, among other things, that if you take this idea seriously, then thinking of the space of reasons broadly enough to encompass not only beliefs but also knowledge is not an optional extra. There is no purely internal space of reasons. To understand how experience can be part of the logical space of reasons, and so how our thoughts can have any content at all, we need to understand how a subject can be open to the way things manifestly are, where this involves knowing about what is going on around you.

Setting aside conceptual roles, the priority of knowledge may provide an adequacy condition for the theory of content. Suppose there was a kind of content or a kind of representation that could not distinguish a situation in which water is wet from a situation in which something that merely looks, smells, feels, and tastes like water is wet. A picture in the head, qualitatively conceived, may be such a representation. Accepting this kind of representation or content could never constitute knowledge, since there would not be the right kind of distinction between justification and knowledge. If one of your beliefs about barns constitutes knowledge, then it matters whether or not there are fake barns in your neighborhood. If believing something about barns were a matter of accepting one of these phony propositions that cannot distinguish between real and fake barns, then it would not matter whether the barns were real or fake. According to the priority of knowledge, if these representations are not even candidates for knowledge, then they are not to be believed.

## CONTACT

What justifies this preoccupation with knowledge? Each account of something in terms of knowledge must of course be judged on its own merits, but is there anything special about knowledge that holds them all together? A

true belief will match or accurately represent the world, but knowledge seems to involve a kind of contact with the world. The recognition of the importance of this kind of contact is one of the underlying ideas that unifies these various approaches.

Edmund L. Gettier (1963) shows that justified, true belief alone is not sufficient for knowledge. If a justified, true belief is inferred from a false premise, then it will not constitute knowledge, even if that premise was justified. Not all cases of justified, true belief without knowledge involve inference from a false belief. Alvin I. Goldman (1992) imagines a case in which you look at a barn that is surrounded by realistic barn facades and form the justified, true belief that it is a barn. You do not know even though you are right because you just got lucky. Though you do get lucky, and it is just an accident, we cannot deny that your belief about the barn is causally connected to the barn. If we were trying to understand knowledge in terms of being in contact with the world, then we would need to specify the right kind of contact. But if you are using the notion of knowledge to explain other things, then it is easy to say what kind of contact you have in mind: you are connected in the right way to *p* if you know that *p*.

The presence or absence of this kind of contact matters in a variety of areas in philosophy. For example, as Unger argues, a factive propositional attitude either entails knowledge or the absence of knowledge. If you are happy that it is raining, or you notice that it is raining, then it follows that it is raining. These propositional attitudes are factive. Moreover, if you are in one of these mental states, then it also follows that you know that it is raining. By contrast, if you forget that it is raining, then it still follows that it is raining. Forgetting that *p* is just as factive as being surprised or embarrassed that *p*, but if you forget or are unaware that *p*, then it does not follow that you know that *p*. It follows that you do not know that *p*. Not all factive attitudes entail knowledge. But they do not leave the question of knowledge open. As Robert Gordon (1969) points out the propositional emotions, even the nonfactive ones, do not leave open the question of knowledge either. If you fear, hope, or are worried that *p*, then it does not follow that *p*. But it does follow that you do not know whether or not that *p*.

What matters in all these cases is genuine contact with the world, rather than merely a match between what is inside and what is outside the mind. You might be happy when it rains without being happy that it rains. You need the right kind of connection between the rain and the happiness for the happiness to be about the rain.

If the disturbing sight of the rain leads to your taking certain kinds of medication, then the rain, and your knowledge thereof, may cause the happiness, but you will not necessarily be happy that it is raining. The rain is causally related to the happiness, but not in the right way. What is the right way? It looks like the happiness has to be connected to the rain in the same way that a belief has to be connected to a fact for the belief to constitute knowledge.

Whenever something interesting requires contact between the mind and the world, a causal theory of that thing will at least look plausible. But any such theory will be faced with deviant causal chains: cases where there is a causal connection, but not the right kind of causal connection. You might intend to run over your uncle, and this may lead you to back your car out of your driveway to drive to his house. But if, unknown to you, your uncle is napping behind the wheels of your car, you will run him over; your intention to run him over will cause you to run him over; but you will not, in this case, run him over on purpose. Your intention to A is causally related to your A-ing, but not in the right way, so you do not intentionally A. This is a deviant causal chain.

Here is one thing to notice about the case. You correctly believe that backing out of your driveway will lead to running over your uncle. Given your plan, the belief, we may say, is justified. But the belief does not constitute knowledge. If it is just an accident that your belief is true, and you act on that belief, then it will just be an accident that your attempts are successful, if they are successful at all. To get intentional action, your means-ends beliefs must constitute knowledge. This is one suggestion for ruling out causal deviance in action theory. If this is right, then it not only follows that we can explain particular actions in terms of particular states of knowledge. It at least suggests that we understand intentional action, one kind of contact between the mind and the world, in terms of knowledge. Unless we also have to understand knowledge in terms of action, it looks as though knowledge is the more fundamental notion.

## KNOWLEDGE AND BELIEF

The nature of knowledge has been a central problem in philosophy from the earliest times. One of Plato's most brilliant dialogues, the *Theaetetus*, is an attempt to arrive at a satisfactory definition of the concept, and Plato's dualistic ontology—a real world of eternal Forms contrasted with a less real world of changing sensible particulars—rests on epistemological foundations.

The problem of knowledge occupies an important place in most major philosophical systems. If philosophy is conceived as an ontological undertaking, as an endeavor to describe the ultimate nature of reality or to say what there really is, it requires a preliminary investigation of the scope and validity of knowledge. Only that can reasonably be said to exist which can be known to exist. If, on the other hand, philosophy is conceived as a critical inquiry, as a second-order discipline concerned with the claims of various concrete forms of intellectual activity, it must consider the extent to which these activities issue in knowledge.

In modern philosophy in the widest sense of the phrase—that is, philosophy since the Renaissance—theory of knowledge has usually been the primary field of philosophical investigation. René Descartes and John Locke, David Hume and Immanuel Kant, were all, in the first instance, epistemologists. Epistemological considerations played an important part in the work of Arthur Schopenhauer, but they were less central in G. W. F. Hegel and Friedrich Nietzsche, who were more occupied with the nature of the human mind in general and with the institutions within which it is exercised than with its more narrowly cognitive aspects. With Søren Kierkegaard and his existentialist descendants the focus of interest was man's will rather than his intellect. Anglo-Saxon philosophy, however, has remained epistemological. J. S. Mill, Bertrand Russell, and the analytic philosophers of the

twentieth century continued to work in the area marked out by Locke and Hume. Even the British Hegelians of the late nineteenth century, the school of Thomas Hill Green and F. H. Bradley, were led into far-reaching epistemological studies by the character of the native tradition they were seeking to overthrow.

Belief has had less attention from philosophers. It has generally been taken to be a more or less unproblematic inner state, accessible to introspection. But there has been disagreement about whether it is active or passive, Descartes having contended that assent is a matter of will, Hume that it is an emotional condition in which one finds oneself. Alexander Bain urged that belief should be interpreted in terms of the tendencies to action with which it is associated, and Charles Sanders Peirce took the view that it is an unobstructed habit of action that, like health, comes to our notice only when we have lost it. Faith, especially religious faith, and probability, the logic of rational belief, have been thoroughly examined, but belief itself has received surprisingly cursory treatment.

### THE DEFINITION OF KNOWLEDGE

According to the most widely accepted definition, knowledge is justified true belief. That it is a kind of belief is supported by the fact that both knowledge and belief can have the same objects (thus, half an hour ago I believed I had left my raincoat in the garage; now I know that I have) and that what is true of someone who believes something to be the case is also true, among other things, of one who knows it. One who comes to know what he formerly believed does not lose the conviction he formerly had.

It is obvious and generally admitted that we can have knowledge only of what is true. If I admit that *p* is false, I must admit that I did not know it and that no one else did, although I may have thought and said so. It is urged, on the ground that beliefs that merely happen to be true cannot be regarded as knowledge, that knowledge must be justified. I may draw a true conclusion by invalid means from false premises or believe a truth on the strength of a dream or the misremembered testimony of a notorious liar. In such cases as these I do not really know the things I believe, although what I believe is true. There are, however, objections to all three parts of the definition of knowledge as justified true belief.

**TRUTH.** It has been suggested that the requirement that what is known be true is excessively stringent. Complete certainty of a statement's truth is not to be had; the best we can achieve is very strong grounds for thinking it true.

Thus, if knowledge entails truth, we can never attain knowledge or, at any rate, never know that we have done so. This objection is misconceived. If I firmly believe that something is true on what I take to be sufficient grounds, I am right to say that I know it. It may be that the grounds are, in fact, insufficient and that what I claim to know is false. In that case my claim is mistaken, but it does not follow that I was wrong to make it in the sense that I had no justification for doing so.

It has also been argued, with a view to showing that knowledge and belief are quite distinct and unrelated, that whereas beliefs can be true or false, knowledge is neither. This argument exploits the fact that we speak of a belief but not of a knowledge, only of a piece or item of knowledge. Furthermore, since all items or pieces of knowledge are by definition true, we never need to speak of them as true items or pieces in order to distinguish them from false ones.

**BELIEF.** It is often objected that knowledge cannot be a kind of belief, even though they can have the same objects, because they exclude each other. If I know that  $p$ , it would be wrong for me to say that I believe it, since this would suggest that I do *not* know it. If, knowing  $p$ , I am asked “Do you believe that  $p$ ?” I should reply “No, I know it.” This is hardly a serious argument. I should mislead people if I described my wife as the woman I live with, and I might say, “No, she’s my wife,” if I were asked whether she is the woman I live with. Nevertheless, my wife is the woman I live with. What is true is that I do not *merely* live with her. Likewise, if I know that  $p$ , I do not merely believe it, but I do believe it all the same. It is often wrong or misleading in certain circumstances to say something that is unquestionably true. The boy who, having taken two jam tarts, answers the question “How many have you had?” by saying “One” has told the truth but not the whole truth.

A more powerful argument against the definition of knowledge in terms of belief is that people can, it seems, know something to be the case and yet refuse, or be unable to bring themselves, to believe it. A woman told by wholly reliable witnesses with a wealth of circumstantial detail that her husband has been killed in an accident might be in this position. One way of getting around this objection is to say that she believes both that her husband is dead and that he is not. It is possible and not uncommon to believe something and its contradictory. It is not possible both to believe something and to not believe it at the same time, and what she will say is, “I don’t believe it,” although what she means is that she believes it is false.

Another possibility is to say that although she has conclusive grounds for believing that her husband is dead, she does not, in fact, believe it and does not know it either. To have conclusive grounds is one thing; to recognize that they are conclusive is another.

It should be noted that where knowledge and belief overlap, the kind of knowledge involved is propositional knowledge, or what Gilbert Ryle called “knowing that.” There is also “knowing how” (to skate, tie a reef knot, do long division), where there are no propositions to be true or false and where knowledge can vary in degree. The two kinds of knowledge are connected in that both are the outcome of learning. Belief is always propositional or believing that; there is no believing how that serves as a defective version of knowing how to do something.

**JUSTIFICATION.** We often express unreasonable hunches or intuitions by saying, “I know,” and if they turn out, to our gratified amazement, to be correct, we rejoice by saying, “I knew it.” Does this show that true belief can be knowledge even without justification? The emphasis we put on the verb when we use it in such a case suggests that it is an abnormal or marginal use. It is generally accepted that lucky guesses should not count as knowledge.

An important difficulty arises from the requirement that true belief must be justified if it is to be knowledge. What is it for a belief to be justified? One obvious answer is that my belief in  $q$  is justified if there is some other belief  $p$  that entails or supports it. It is clearly not enough that this further belief  $p$  should merely exist. It must also be a belief of mine; I must know it to be true, and I must know that it justifies  $q$ . But if this is a definition of justification, the original definition of knowledge is rendered circular and generates a regress. It has the consequence that before any belief can be justified, an infinite series of justifications must already have taken place.

How can such a regress be halted? A natural step is to ask whether all justification has to be of this propositional or inferential kind. As Russell has observed, we can define derivative knowledge in this way but must add an account of intuitive or uninferred knowledge. Philosophers have fastened on two forms of intuitive knowledge that, by standing as the uninferred first premises of all inference, can terminate the regress of justification. First, there are self-evident necessary truths, and, second, there are basic contingent statements, immediately justified by the experiences they report and not dependent on the support of any further storable items of knowledge.

In the first group are the axioms of logic and mathematics, such as the law of excluded middle and the principle of the commutativity of addition ( $a + b = b + a$ ), and statements that correspond to familiar verbal definitions, such as that kittens are young cats. Some philosophers hold that such intuitive, necessary truths record the results of intellectual intuition, the direct inspection of the relations of timeless universals; others, that their truth is essentially verbal in character, that one must accept them in order to be regarded as understanding the ordinary meaning of the words they contain. To accept an intuitive, necessary truth is to be ready to draw inferences in accordance with it. If I understand and accept the truth of “If (if  $p$ , then  $q$ ), then (if not- $q$ , then not- $p$ )” I must regard the deduction of “If he’s not over twenty-one, he’s not eligible” from “If he’s eligible, he’s over twenty-one” as valid. By applying such rules of inference to intuitive necessary premises, further demonstrative necessary truths are arrived at.

Intuitive contingent truths have been held to be those that describe the immediate objects of perceptual or introspective experience—for example, “There is a green patch in the middle of my visual field” or “There appears to me to be a green flag here” and “I am in pain” or “I want to go to sleep.” Basic statements like these are said to be incorrigible in the sense that they are wholly certified by the experiences they report and are logically immune from falsification by the results of any further experience. There may be no green flag here, but whatever may happen, there does now appear to be one. I may find it impossible to go to sleep once I get into bed, but I still want to go to sleep now. A statement is incorrigible if its truth follows from the fact that it is believed by the person to whom it refers. Thus, although I can make such a statement falsely, I must know that the statement is false when I do so. I cannot be honestly mistaken about my pains or the contents of my visual field.

It has sometimes been denied that there are any contingent, empirical statements that are basic and incorrigible in this sense. Coherence theories of knowledge have been propounded by the absolute idealists of the late nineteenth century and by C. S. Peirce, Karl R. Popper, and W. V. Quine in more empiricist forms in which beliefs are seen as justifying one another but none as in any sense self-justifying. To overcome the apparent circularity of the doctrine, it has been argued that some beliefs are relatively basic in that they can be accepted as true by some kind of convention or posited for the time being but that the element of dogmatism involved is only provisional and is open to revision.

PLATO’S *THEAETETUS*. Several of the points raised concerning truth, belief, and justification were first made in the *Theaetetus*, that most modern in spirit of Plato’s dialogues. In it three definitions of knowledge are examined, and in the end all are rejected. The three are that knowledge is (1) perception or sensation, (2) true belief, and (3) true belief *meta logou*, translated by John Burnet as “accompanied by a rational account of itself or ground.” Against the view that knowledge is true belief Plato made the point that lawyers can persuade juries to accept beliefs that are, in fact, true by using rhetorical devices but cannot be said to provide them with knowledge by doing so. Against the third definition, which, in effect, takes knowledge to be justified true belief, he pointed out that it is circular and regressive.

There is an obvious objection to the definition of knowledge as perception. Perception itself must be defined in terms of knowledge—namely, as the acquisition of knowledge about the external world by means of the senses. Plato’s meaning here is perhaps better rendered by understanding his first definition to equate knowledge and sensation. Certainly this makes more plausible Plato’s identification of this definition with Protagoras’s thesis that man is the measure of all things (or that the truth for each man is simply what appears to him to be the case). In fact, Protagoras’s thesis would be more accurately interpreted as the view that knowledge and belief are one and the same. This contention has obviously contradictory implications, as Plato pointed out. We all believe some beliefs of others to be truer than our own, and most people believe that Protagoras’s theory is false. Something like that theory persists, however, in the view, to which we shall later return, that the foundations of empirical knowledge consist of incorrigible statements about immediate experience. According to this view, what we believe about our current sensations or experiences, whatever we may choose to say about them, is true. If it is also correct that such sensations are self-intimating, in the sense that they cannot occur without our knowing them to occur, it follows that every sensation is an item of knowledge though not that every item of knowledge is a sensation.

In his discussion of knowledge as true belief Plato raised the problem of false belief. How can we believe falsely that  $X$  is  $Y$  since if the belief is false, there is no  $X$  that is  $Y$  to form a belief, true or false, about? A false belief, it seems, is no belief at all. A perhaps oversimple solution to the problem is that we can know a thing  $X$  well enough to be able to identify it as a subject of discourse without knowing everything about it (whether, for

instance, it is *Y* or not-*Y*). This draws attention to the point that the objects of knowledge are not always propositional, that not all knowledge is knowledge that. In addition to the knowledge how emphasized by Ryle, there is knowledge with a direct object, or knowledge of, claimed in such remarks as “I know Jones” or “I know Paris.”

A claim to know a person can be intended and understood in two main ways. In saying that I know Jones, I may mean that I have met him and that I could not recognize him (and, usually, that we have had enough to do with one another for him to remember me). On the other hand, I may mean that I know what his character is like, what sort of things he is likely to do. According to the first interpretation, very little knowing that is involved, although I should be expected to be capable of giving some description of Jones’s appearance; according to the second, some knowledge that relating to his character is implied, but none about his past history, health, occupation, and so on is.

A claim to know a place is ordinarily a claim to knowledge how, to an ability to find one’s way about in it. It is not enough simply to have been there. Among other individual objects of knowledge are games, languages, and works of art. The last of these kinds of knowledge can be treated in much the same way as knowledge of persons; the others, as cases of knowing how, as claims to the possession of a skill. In general, knowledge of can be reduced to varying mixtures of knowing how and knowing that, though by no single recipe. It never involves a claim to knowledge that of all the facts involving the individual in question. A further point against Plato is that I can know enough about an individual or a thing to be able to refer significantly and successfully to him or it without being in a position to say that I know him or it *simpliciter*. I know enough about Samarqand to refer to it as a city in Uzbekistan and to ascribe to it a degree of beauty, historical interest, and size, but I do not know Samarqand at all, for I have never been there and could not find my way about in it.

**IS KNOWLEDGE DEFINABLE?** The English philosopher John Cook Wilson (1849–1915), closely followed in this by his disciple H. A. Prichard (1871–1947), strenuously maintained that the concept of knowledge is primitive and indefinable. Against such idealist logicians as F. H. Bradley and Bernard Bosanquet, they argued that judgment is not a genus of which knowledge, belief, and opinion are species. A judgment, said Wilson, is the conclusion of an inference, but some knowledge must be

uninferred. Nor is knowledge a kind or species of thinking or a species of belief, for belief rests on knowledge in that it requires that there should be both some known evidence for it and the knowledge that this evidence is insufficient. No doubt, belief usually does rest on evidence or what is taken to be evidence, but it is not, as Wilson supposed, necessary that it should do so. I may believe a woman to be married because I take her to be wearing a wedding ring. The fact that it is not a wedding ring that she is wearing does not in the least imply that I do not really believe what I infer from my mistake.

According to Prichard, knowledge is completely *sui generis* and cannot, as he put it, “be explained.” We cannot, he said, derive knowledge from what is not knowledge. This observation, if it is relevant at all, is simply a dogmatic assertion of the indefinability of knowledge. We can certainly define some things in terms of what they are not; for instance, not all cats are kittens, and not all young things are kittens, but a kitten is by definition a young cat. Knowledge and belief, Prichard held, are utterly distinct and cannot be mistaken for each other. We know directly and infallibly whether our state of mind is one of knowledge or belief. If so, knowledge and belief could not be related as genus and species, although they could still be different species of the same genus, another possibility that Prichard ruled out. His view that the two cannot be mistaken for each other seems clearly mistaken. We often claim with complete sincerity to know things that turn out to be false in the end. In so doing, we have taken a belief, mistakenly, to be knowledge.

Is the opposite possibility ever realized? Do we ever take to be mere belief something that, in fact, we really know? Is there a difference between knowing something and knowing that we know it? Benedict de Spinoza held that there is not. “He who has a true idea, knows at that same time that he has a true idea, nor can he doubt concerning the truth of the thing” (*Ethics*, Part 2, Proposition 43). As Spinoza expressed it, the doctrine is plainly false. I can perfectly well have very little confidence in a belief that is really true if, for example, it has been communicated to me by a notoriously unreliable informant. In other words, I can have a belief that is really true without knowing that it is true. But can I know that something is the case without knowing that I know it? I can certainly have a justified true belief without knowing that that is what it is, for I may not realize that the grounds I have for believing it really do justify it. The question deserves a more thorough investigation than it can be given here.

**RATIONALIST THEORY OF KNOWLEDGE.** Plato's distinction between knowledge and belief has had a greater influence on the subsequent course of philosophy than his penetrating but unsuccessful attempts to find a definition of the concept. His essential point was that knowledge and belief are not only distinct attitudes but that they also have distinct and proprietary objects. Knowledge can be only of what is eternal and unchanging, of Forms, Ideas or universals; belief has for its objects the changing sensible particulars that make up the temporal world. Plato's reflections on mathematics seem to have led him to this conclusion. The propositions of geometry are preeminently objects of knowledge in that they can be established as conclusively true, once and for all, by demonstrative reasoning. Our beliefs about matters of temporal fact, on the other hand, are much more liable to illusion and error. The sensible objects of perceptual belief are infected with contradiction; they undergo change and have contrary properties at different times. But the objects of mathematical knowledge are wholly different. The circles and triangles studied by geometers are exact and perfect; they are ideals that the circular and triangular things we perceive with the senses approximate but always fall short of.

There are three ways in which a circular concrete thing may not be really circular. It may be circular at one time and elliptical at another; it may be other things (for example, green, cold, and sweet) as well as circular; and as concrete and sensible, it may not be strictly or perfectly circular. From these facts Plato concluded that such a thing is not wholly real in the way that the ideal circle of the geometer is. The ideal circle is a genuine object of knowledge, and only such wholly knowable things can be wholly real. From the distinction between knowledge and belief, then, Plato derived a distinction between two sorts of object, each sort constituting a separate world of its own—the abstract world of eternal Forms, which is the knowable reality, and the concrete world of changing particulars, which is only appearance, not nonexistent but not wholly real either, and of which one can have not knowledge but only belief.

Plato's arguments for the unknowability and unreality of concrete, sensible things are not very persuasive. If this once circular mat is now elliptical, it does not follow that it was not really circular before. If this circular object is also green and cold, that does not in any way detract from its circularity. Finally, even if it is not perfectly circular, it may be quite definitely green. In general, there would seem to be many propositions that are known by some people but only believed by others; a mathemati-

cian will know the truth of a proposition he has proved, whereas another person will simply believe it on his authority. Some things I now know I used only to believe—for instance, that I should be writing this here today; some things I now only believe I once used to know—for instance, where I bought my raincoat. These considerations show that the objects of knowledge and belief are not wholly mutually exclusive. But it may still be true that there are some things that can be only believed, whereas others can be both believed and known.

At the center of Plato's thinking about this subject is a principle that defines one important sense of the word *rationalism*—the principle that only necessary truths, established by a priori reasoning, can really be known. Something like this principle was accepted by Aristotle, although he rejected Plato's doctrine that Forms or universals occupied a separate abstract world of their own beyond time and space. Aristotle agreed that only the form of things could be known and that the matter that individuated or particularized them was beyond the reach of knowledge. For him true knowledge was to be attained by a process of intuitive induction that discerned the necessary connections between the forms present in concrete things. A science or ordered body of knowledge must consist of propositions deduced from self-evident first principles of this kind.

Descartes's rationalism was inspired by the reflection that ordinary claims to knowledge often prove mistaken. True knowledge, he insisted, must be objectively certain and impossible to doubt. His methodical endeavors to doubt everything were brought up short by the celebrated "I think, therefore I exist." I cannot doubt that I doubt, for in the act of doubting it I prove it to be true; if I doubt, I think; and if I think, I exist. What, he then inquired, is so special about *cogito* and *sum*? What makes them so indubitably certain? His unhelpful conclusion is that they are clearly and distinctly perceived to be true. What he meant by this weakly formulated criterion of certainty can best be discovered by seeing what, in practice, he took it to certify. It appears that two sorts of proposition are clearly and distinctly perceived to be true: (1) necessary truths whose denial is self-evidently contradictory and (2) the immediate deliverances of sensation and introspection about one's own current mental state. Premises of both kinds figure in his first proof of God's existence:

Every event must have an adequate cause.

I have a clear and distinct idea of God.

God alone is an adequate cause for my idea of him.

Therefore, God exists.

In fact, *cogito*, I think, is not a clear instance of either, let alone both, of these two kinds of knowable, and even if it were, it would not follow from its being, on one hand, necessary and immediate and, on the other, certain that anything else that was necessary and immediate was also certain. Descartes's primary certainty was perhaps first thought of on a Thursday, but it does not follow that anything first thought of on a Thursday either by him or by anyone else is certain, too. It is not a necessary truth that I think or exist, for I might not be awake and might never have existed. If this is the case, the facts in question could not, of course, have been expressed in the first person singular.

Locke, despite his justly recognized position as a founding father of empiricism, reached much the same rationalist conclusion as Descartes, although by a very different route. He defined knowledge as "the perception of the agreement or disagreement of two ideas" (*Essay concerning Human Understanding*, Book 4, Ch. 1, Sec. 2). He went on to distinguish three kinds of knowledge: (1) intuitive knowledge of such things as the fact that red is not green and the fact of one's own existence; (2) demonstrative knowledge, which includes mathematics, morality, and the existence of God; and (3) sensitive knowledge, which is concerned with "the particular existence of finite beings without us." The third type of knowledge does not conform to his general definition, as he admitted. To become aware of a finite being outside us, we have to infer the existence of something that is not an idea from the ideas of sensation we take it to cause, and in part, to resemble. Locke's definition, as he understood it, restricts knowledge to the domain of a priori necessary truths. In intuition and demonstration there is a direct or indirect awareness of the connection between ideas present to the mind. But in the third case a connection is asserted between an idea of sensation and a physical thing that is not and cannot be directly present to the mind.

Locke did not introduce a special category to accommodate our knowledge of the ideas we passively experience but remitted them in passing to the category of intuitive knowledge. This sort of knowledge is quite unlike his exemplary cases of intuition, being contingent and empirical where the exemplary cases are necessary and a priori, and he might well have introduced a special category of reflective knowledge to accommodate it. It would comprise assertions of the connection of particular ideas, whereas intuition and demonstration would cover the connections of abstract, general ideas. Thus, although Locke's official definition of knowledge confines its application to necessary truths, it could, with a

little modification, have been extended to cover a person's awareness of the present contents of his mind. But it could not, by any contortions, have been made to cover sensitive knowledge of real existence, that empirical knowledge par excellence which it was Locke's avowed purpose to justify and explain.

**CERTAINTY.** The indestructible vitality of the rationalist theory that necessary truths alone or necessary truths and reports of immediate experience are really knowledge was proved by its wide acceptance among empirically minded philosophers of the twentieth century—for example, Russell, C. I. Lewis, and A. J. Ayer. In support of it a powerful battery of arguments was produced, designed to show that despite the subjective certainty we feel in many kinds of belief, they cannot count as knowledge because they are not objectively certain.

Russell contended that all the sources of what we ordinarily regard as common knowledge of fact are in some degree untrustworthy. Perception is tainted by illusions, hallucinations, and dreams. Memory is notoriously fallible. Testimony, which plays such a large part in building up the social fabric of belief, presupposes an inference to other minds that is inevitably shaky and conjectural. Induction never certifies its conclusions, imparting at best only a measure of probability to them. Even introspection, if it is held to convey information about the self as a continuing personality, goes beyond what is directly present to the mind. Only what is directly present to it—currently occurring thoughts and feelings—is the object of certain, infallible, and indubitable belief.

Lewis generalized Russell's position by distinguishing expressive judgments that report current states of mind from all other empirical propositions on the ground that they alone are wholly nonpredictive and have no implications about future observable happenings by whose failure to occur they might be refuted. Ayer, at one time, went even further. He held that all contingent, empirical propositions whatsoever, including reports of immediate experience, are uncertain on the ground that every such proposition involves the application of a general predicative term to its subject and thus makes a comparison with previous and perhaps faultily remembered instances of the term's application.

This kind of fallibilism about empirical belief was doggedly resisted by G. E. Moore and, after him, by Ludwig Wittgenstein, J. L. Austin, and Norman Malcolm. Moore's main point was that the word *certain* is learned and thus acquires its meaning from such situations as that in which a man holds up his hand and makes the

perceptual judgment “I know for certain that this is a hand.” Some rather subtler arguments are sketched in his book *Philosophical Papers*. Their general upshot is that the rationalists and fallibilists have been working with an unconsidered and excessively stringent concept of certainty. They have simply taken it for granted that for a belief to be certain, it must be impossible to doubt it. Russell, for example, began his search for certain knowledge with the question “Is there any knowledge in the world which is so certain that no reasonable man could doubt it?”

There are at least four senses in which it may be held that a belief cannot be doubted. The first is psychological; a man cannot doubt a belief if he cannot, in fact, bring himself to suspend judgment about it. This kind of certainty will vary from person to person and is of no direct philosophical interest. The second sense is logical. Here “doubt” is taken to mean “suppose false” and “can” to mean “can without logical inconsistency.” This yields the strict rationalist view, since only necessary truths cannot be supposed false without inconsistency. A third sense identifies certainty with incorrigibility. According to it, a belief cannot be doubted if its truth follows from the fact that it is believed. Anyone who doubts an incorrigible belief shows that he does not understand the words that express it. The favorite examples of incorrigible beliefs are reports of immediate experience, such as “I am in pain” or “It seems to me now that there is a table here.” But the notion would also apply to the more elementary and intuitive kind of necessary truth, such as the law of contradiction. Finally, there is the concept of certainty that, say Moore and his adherents, we actually employ in common speech where it means what cannot reasonably be doubted or supposed false. That people make all sorts of mistakes is not, according to this view, a reason for doubting the truth of a particular proposition. What is required to justify doubt is that propositions just like this, made in circumstances just like these and resting on just this kind of evidence, have in the past turned out to be mistaken. In this sense of certainty many beliefs based on perception, memory, testimony, and induction are objectively certain and thus properly regarded as items of knowledge. This view has the merit of allowing that many propositions that are, in fact, necessary truths are or once were less than certain, and it does not require the theory that there are any incorrigible propositions to be accepted. A further point in its favor is that such surprising theses as the one that no factual belief is certain can surprise us and escape triviality only if they are taken in this sense.

**SOME MODERN VIEWS.** In the mid-twentieth century, philosophical discussions of knowledge were much concerned with three distinctions drawn by Russell, Ryle, and Austin that must be briefly mentioned.

*Acquaintance and description.* In Russell’s early writings he drew a distinction between knowledge of things and knowledge of truths, between knowledge of and knowledge that, a distinction marked in French by the verbs *connaître* and *savoir*. Within each kind he also discerned a distinction between an immediate and a derived form. Immediate knowledge of truths is conveyed in intuitive statements—for example, basic judgments of perception and the axioms of logic and mathematics; derivative knowledge of truths, in demonstrable necessary propositions and inferred empirical statements. Parallel to this on the side of knowledge of things is the distinction between knowledge by acquaintance and knowledge by description.

Acquaintance, as Russell defined it, is the converse of presentation; it is the direct and infallible apprehension of some sort of object. But objects of description, unlike those of acquaintance, can fail to exist. Russell held that we are acquainted with present and past particulars and also with universals. This doctrine has led to a good deal of confusion. Certainly we do know things, persons, and places by acquaintance, but to do so is generally to know that something is true of them and is at least to know how to recognize them. The words with which we refer to things we are not acquainted with can be defined or explained in terms of those connected with objects of acquaintance. But this produces understanding rather than knowledge, understanding of singular terms (whether what they purport to refer to exists or not) and of general terms (whether or not there is anything they apply to). Russell’s principle of acquaintance (“Every proposition which we can understand must be composed wholly of constituents with which we are acquainted”) is really a version of the empiricist theory of meaning. Asserted without qualification, it is highly unpalatable. We are not acquainted with anything corresponding to the “if” that occurs in the verbal expression of a hypothetical proposition although we understand the word. In general, to become acquainted with things is to acquire some intuitive knowledge of truths in which they figure, particular objects of acquaintance being the subjects of such truths and universal objects of acquaintance their predicates. In other words, knowledge of things cannot be separated from and regarded as prior to knowledge of truths in the way Russell supposed.

*Knowing how and knowing that.* Ryle's distinction between knowing how and knowing that has already been mentioned. There is a parallel distinction between remembering how and remembering that (there is also memory of past events). Ryle is anxious to correct the intellectualist bias of theorists of knowledge and to draw attention to the dispositional nature of all kinds of knowledge and belief; we speak, after all, of the knowledge and beliefs of those who are fast asleep. He tends to suggest that knowing that is a special, verbal form of knowing how, that it consists in having learned how to answer certain questions and now being ready to answer them.

*Performative and descriptive verbs.* John Austin's work on performative utterances has interested many philosophers in that class of verbs that are used in the first person present to do things rather than to describe what is being done. Examples of such performative verbs are "promise," "swear," "take thee, X, to be my wedded wife," and "name this ship Y." A verb  $\phi$  is performative if it follows that I  $\phi$  from the fact that I say, "I  $\phi$ ." Austin appears to have thought, wrongly, that "know" is a verb of this kind and that its function is to guarantee or authorize the acceptance of the piece of information that followed it. It is true that to prefix "I know" to a statement of fact does not add much to its content. But  $p$  and "I know that  $p$ " are not equivalent, since the former may be true when the latter is false. Austin was right in denying that knowledge is a state of assurance stronger than the most assured belief, though it is not clear that anyone ever supposed that it was. But the correctness of this denial, although it entails that it is not some describable psychological feature of the knower's state of mind that differentiates knowledge from belief, does not entail that the difference is not at all describable and lies, rather, in some nondescriptive function that the word performs.

## THE NATURE OF BELIEF

Most philosophers who have in any way adverted to the nature of belief have assumed that belief is an inner state of mind, directly accessible to introspection and distinct from, though causally related to, the believer's behavior. In *The Emotions and the Will* (1859) the Scottish philosopher Alexander Bain proposed that belief should be defined in terms of behavior: "Belief has no meaning except in reference to our actions ... no mere conception that does not directly or indirectly implicate our voluntary exertions can ever amount to the state in question." In support of Bain's theory is the fact that not only can others check our claims to believe by considering whether

we behave appropriately but we ourselves may also take the results of such a test to overrule claims to believe that we have sincerely made.

Careful statements of the opposing doctrines were given by H. H. Price and R. B. Braithwaite. Price's mentalist definition of belief equates it with entertainment of a proposition together with assent. To entertain a proposition is to understand and attend to its meaning; when it occurs by itself, it is neutral and uncommitted as regards the proposition's truth or falsehood. Price breaks assent down into a volitional and an emotional part. He describes the volitional element as a mental act of preferring a proposition to any incompatible alternatives that have occurred to one; the emotional element is a feeling of conviction or assurance and may vary in degree. Braithwaite identifies belief in a proposition with its entertainment together with a dispositional readiness to act as if it were true. "Being ready to act as if  $p$  were true" has at first sight a suggestion of circularity, for it seems to mean being ready to act as if one believed  $p$ . But this can be avoided. I act as if  $p$  were true if I act in a way that would satisfy my desires if  $p$  were in fact true.

Against both theories it should be said that "entertainment" is dispensable if the normal sense of "believe" is in question, for we attend consciously to the propositions we believe only at rare intervals. As regards Price, what is to be understood by an act of preferring as opposed to an emotion of preference? It looks very like the silent assertion of the proposition itself, an inner rehearsal of a piece of outward verbal behavior. Second, feelings of conviction do not always attend even the beliefs we consciously entertain. Unless our confident beliefs are actually challenged, our state would seem to be one of easy and unemotional taking for granted.

Against the view of Bain and Braithwaite it has been urged by Mill, Franz Brentano, and Russell that if a belief has behavioral effects different from mere entertainment, it must differ in its intrinsic mental character. This is a misunderstanding. For a behaviorist there is a difference in the dispositions of one who believes and of one who merely entertains a proposition. A more serious difficulty is presented by beliefs that have negligible practical consequences, such as those about remote historical or astronomical events. But even here there is a disposition to verbal behavior, and, again, a disposition can exist without being actualized. There is also the difficulty that my claims about what I believe become, according to this theory, inductive conjectures about what I should do if certain circumstances arose. One reply is that not all inductive conjectures are conjectural to that degree. I

need not, for example, feel very hesitant about what would happen if this iron table were dropped on that china teapot. Braithwaite adds that his theory has the merit of making possible rather precise measurements of subjective probability or degree of belief. The numerical probability I attach to a belief can be regarded as the least favorable odds I should accept on its turning out to be correct. Thus, unless I accept an odds-on bet, I do not believe something more than I believe its denial.

There is an interesting and extreme opposition in the history of philosophy between Descartes, who held that assent is a matter of will that can be freely given or withheld, and Hume, who represented us as largely passive in belief, which he conceived as a feeling that we find ourselves with and must put up with whether we like it or not, much as we find ourselves equipped with desires and aversions. Descartes's activism is shown first in his proposal that the philosopher should undertake a course of methodical doubt, suspending judgment about all the beliefs he has hitherto taken for granted. It reaches its fullest development in his attempt to solve the theological problem of error or intellectual evil, to reconcile the fact, on which his whole philosophy depends, that many of our beliefs are false with the goodness of God. The solution he offered is that God has fitted us out with limited intellects, appropriate to our earthly needs, but in his own image, with unrestricted freedom of will. When we make mistakes it is because we have culpably given free assent to propositions beyond the effective reach of our limited intellects.

In Descartes's favor is the fact that we do assess beliefs as more or less reasonable, a practice whose theory is logic and methodology. And the ethics of belief has not always been confined to distinguishing logically reasonable beliefs from others. It has often been held that some beliefs—in the existence of God, for example—are morally obligatory, and some beliefs are often recommended as prudent or useful. Hume himself propounded rules for judging causes and effects whose acceptance, he maintained, will enable us to advance science and avoid superstition. On Hume's side is the fact that it seems no more possible to resolve to believe something one actually does not believe than it is to increase one's height or eradicate one's distaste for endives by a simple effort of will. What one can do is to fortify or undermine one's belief in a proposition indirectly by voluntarily concentrating one's attention on the evidence for or against it.

It is quite commonly said that belief must rest on evidence and sometimes, especially by those who hold knowledge to be indefinable, that it must rest on knowl-

edge. It is certainly usual for belief to rest on something the believer regards as evidence, whether or not it is true and whether or not it lends any support to the belief in question. But a wildly dogmatic or superstitious belief, maintained in the teeth of all the evidence, is still a belief, however unreasonable it may be.

**FAITH.** There is some point to the malicious definition of faith as firm belief in something for which there is no evidence, for faith does involve a measure of risk, a voluntary decision to repose more confidence in a proposition, person, or institution than the stable grounds for doing so would, if neutrally considered, justify. Locke defined faith as resting on authoritative testimony, "the assent to any proposition, not thus made out by the deductions of reason, but upon the credit of the proposer." This applies well enough to the religious faith of traditional Christianity, but it is too narrow to cover the general use of the concept. It is often said that science rests on faith in the uniformity and intelligibility of nature as much as religion does on an undemonstrable conviction that the world is under the direction of a wise and benevolent intelligence. Certainly, science would be wholly sterilized if men were not prepared to consider adventurous and unjustified hypotheses. But it is not obvious that these adventurous conjectures have to be believed by their propounders. The austere maxim of W. K. Clifford—"It is wrong, everywhere and for anyone, to believe anything upon insufficient evidence"—is not strictly incompatible with intellectual enterprise. Yet even Popper, who of all theorists of knowledge is most insistent on the conjectural and fallible nature of science, admits that "our guesses are guided by the unscientific, the metaphysical (though biologically explicable) faith in laws, in regularities which we can uncover."

## KNOWLEDGE AND MODALITY

The prominence of the modalities (i.e., necessity and contingency) in epistemological discussions is due to the influence of Immanuel Kant (1965), who maintained that:

- (1) All knowledge of necessary propositions is a priori; and
- (2) All propositions known a priori are necessary.

Saul Kripke (1971, 1980) renewed interest in Kant's account of the relationship between the a priori and the necessary by arguing that some necessary propositions are known a posteriori and some contingent propositions are known a priori. A cogent assessment of the controversy requires some preliminary clarification.

The distinction between necessary and contingent propositions is metaphysical. A necessarily true (false) proposition is one that is true (false) and cannot be false (true). The distinction between a priori and a posteriori knowledge is epistemic. S knows a priori that p just in case: (a) S knows that p; and (b) S's justification for believing that p does not depend on experience. Condition (b) is controversial. On the traditional reading, (b) is equivalent to (c): S's belief that p is nonexperientially justified. Hilary Putnam (1983) and Philip Kitcher (1983), however, argue that (b) is equivalent to (d): S's belief that p is nonexperientially justified and cannot be defeated by experience. Albert Casullo (2003) rejects the Putnam-Kitcher reading on the grounds that it yields an analysis of a priori knowledge that excludes the possibility that someone knows a posteriori a proposition that can be known a priori.

The expression "knowledge of necessary propositions" in (1) is ambiguous. The following definitions remove the ambiguity:

- (A) S knows the *general modal status* of p just in case S knows that p is a necessary proposition (i.e., either necessarily true or necessarily false) or S knows that p is a contingent proposition (i.e., either contingently true or contingently false);
- (B) S knows the *truth value* of p just in case S knows that p is true or S knows that p is false (assuming truth is always bivalent);
- (C) S knows the *specific modal status* of p just in case S knows that p is necessarily true or S knows that p is necessarily false or S knows that p is contingently true or S knows that p is contingently false.

(A) and (B) are logically independent. One can know that Goldbach's Conjecture is a necessary proposition but not know whether it is true or false. Alternatively, one can know that some mathematical proposition is true but not know whether it is a necessary proposition or a contingent proposition. (C), however, is not independent of (A) and (B). One cannot know the specific modal status of a proposition unless one knows both its general modal status and its truth value.

(1) is crucial for Kant, because it is the leading premise of his only argument in support of the existence of a priori knowledge:

- (1) All knowledge of necessary propositions is a priori.
- (3) Mathematical propositions, such as that  $7 + 5 = 12$ , are necessary.
- (4) Therefore, knowledge of mathematical propositions, such as that  $7 + 5 = 12$ , is a priori.

(1), however, is ambiguous. There are two ways of reading it:

- (1T) All knowledge of the *truth value* of necessary propositions is a priori, or
- (1G) All knowledge of the *general modal status* of necessary propositions is a priori.

The argument is valid only if (1) is read as (1T). Kant, however, supports (1) with the observation that although experience teaches that something is so and so, it does not teach us that it cannot be otherwise. Taken at face value, this observation states that experience teaches us that a proposition is true and that experience does not teach us that it is necessary. This supports (1G), not (1T).

Kripke rejects (1) by offering examples of necessary truths that are alleged to be known a posteriori. First, he maintains that if P is an identity statement between names, such as "Hesperus = Phosphorus," or a statement asserting that an object has an essential property, such as "This table is made of wood," then one knows a priori that:

- (5) If P then necessarily P.

Second, he argues that because one knows by empirical investigation that Hesperus = Phosphorus and that this table is made of wood, one knows a posteriori that:

- (6) P.

Kripke concludes that one knows by *modus ponens* that:

- (7) Necessarily P.

(7) is known a posteriori because it is based on (6), which is known a posteriori.

How do Kripke's examples bear on (1)? Once again, a distinction must be made between (1G) and (1T). Kripke's examples, if cogent, establish that (1T) is false: They establish that one knows a posteriori that some necessary propositions are true. They do not, however, establish that (1G) is false: They do not establish that one knows a posteriori that some necessary propositions are necessary. It may appear that Kripke's conclusion that one has a posteriori knowledge that necessarily P entails that (1G) is false. Here a distinction must be made between (1G) and:

- (1S) All knowledge of the *specific modal status* of necessary propositions is a priori.

Kripke's examples establish that (1S) is false: They establish that one knows a posteriori that some necessary propositions are necessarily true. Because knowledge of the specific modal status of a proposition is the conjunction of knowledge of its general modal status and knowledge of its truth value, it follows from the fact that one's knowledge of the truth value of P is a posteriori that one's knowledge of its specific modal status is also a posteriori. However, from the fact that one's knowledge of the specific modal status of P is a posteriori, it does not follow that one's knowledge of its general modal status is also a posteriori.

(1G) has not gone unchallenged. Kitcher (1983) argues that even if knowledge of the general modal status of propositions is justified by nonexperiential evidence, such as the results of abstract reasoning or thought experiments, it does not follow that such knowledge is a priori because the nonexperiential justification in question can be defeated by experience. Casullo (2003) rejects (1G) on the grounds that the Kantian contention that experience can provide knowledge of only the actual world overlooks the fact that much practical and scientific knowledge involves counterfactual conditionals, which provide information that goes beyond what is true of the actual world.

Kripke also argues that some contingent truths are known a priori. His examples are based on the observation that a definite description can be employed to fix the reference—as opposed to give the meaning—of a term. Consider someone who employs the definition description "the length of S at  $t_0$ " to fix the reference of the expression "one meter." Kripke maintains that this person knows, without further empirical investigation, that S is one meter long at  $t_0$ . Yet the statement is contingent

because “one meter” rigidly designates the length that is in fact the length of S at  $t_0$  but, under different conditions, S would have had a different length at  $t_0$ . In reply, Alvin Plantinga (1974) and Keith Donnellan (1979) contend that, without empirical investigation, the reference fixer knows that the sentence “S is one meter long at  $t_0$ ” expresses a truth, though not the truth that it expresses. Gareth Evans (1979) disputes this contention.

## KNOWLEDGE AND TRUTH, THE VALUE OF

Questions concerning the value of knowledge and truth range from those that suggest complete skepticism about such value to those that reflect more discriminating concerns about the precise nature of the value in question and the comparative judgment that one of the two is more valuable than the other.

### THE COMPARATIVE QUESTION AND THE PRAGMATIC ACCOUNT

The history of epistemology has its conceptual roots in the dialogues of Plato, and the question of the value of knowledge and truth arises there as well. In Plato’s *Meno*, Socrates and Meno discuss a number of issues, including the issue of the nature and value of knowledge. Socrates

raises the question of the value of knowledge, and Meno answers by proposing a pragmatic theory: knowledge is valuable because it gets us what we want. Socrates immediately proposes a counterexample, to the effect that true opinion would work just as well: If you want to get to Larissa, hiring a guide who has a true opinion of how to get there will have the same practical results as hiring a guide who knows the way. Meno then voices a philosophically deep perplexity, wondering aloud why knowledge should be more prized than true opinion and whether there is any difference between the two. Meno thus questions two assumptions, the first being the assumption that knowledge is more valuable than true opinion, and the second that knowledge is something more than true opinion.

Socrates’s counterexample suggests another: If you want to get to Larissa, it matters not whether your guide has true opinion or merely empirically adequate views on the matter. To see the counterexample, we need to understand that an empirically adequate theory is one that “saves the appearances,” in other words, one that would never be refuted by any sensory experience. The simplest way to see that such a theory is not the same thing as a true theory is to consider skeptical scenarios such as René Descartes’s evil demon world. The denizens of such a world will have roughly the same views as we do, and their views will be as empirically adequate as ours. Since the demon is so skillful at carrying out his intentions, however, their views will be false even if ours are true. In such a world, there are no guides with true opinions about how to get to Larissa. Instead, the best one could hope for is a guide who has an empirically adequate view of the matter. Yet, if we compare the two situations, the one in the actual world where the hired guide has a true opinion, and the one in the demon world where the hired guide has only an empirically adequate opinion, no suffering accrues to the traveler in the demon world that does not also accrue to the traveler in the actual world, and no benefits are experienced by the traveler in the demon world that are not also experienced by the traveler in the actual world. That is to say, their experiences are indistinguishable, leaving us to wonder what practical advantage truth has over empirical adequacy.

### SKEPTICISM ABOUT THE VALUE OF KNOWLEDGE AND TRUTH

Besides this Platonic threat to the value of knowledge and truth, there are other threats. One arises from the specter of skepticism. If we grant that there is no adequate answer to the skeptic, we might have the experience of philo-

sophical sour grapes, denying the value of what we cannot have.

More respectable threats to the value of knowledge and truth come from positions that question the ordinary thinking that knowledge and truth contribute to well-being. Pyrrhonian skepticism maintains that such ordinary thinking is mistaken, and that the path to happiness requires abandoning a search for knowledge and truth, ridding oneself of beliefs and instead “acquiescing to the appearances.” Arguments for skepticism play an important role in this process insofar as they can play a role in eliminating the dogmatism purportedly inherent in belief, but the Pyrrhonian appeal to skepticism is not simply that of philosophical sour grapes: it is motivated instead by a conception of what human well-being involves and requires.

There is no question that the Pyrrhonian school was sensitive to a real threat to human happiness, for dogmatism has caused immense suffering (for one monumental example, think of the suffering caused by religious wars). It is philosophical overkill, however, to move from such obvious points to skepticism and a denigration of the value of knowledge and truth. For one thing, dogmatism is compatible with a full appreciation of the rights of other human beings and so need not lead to massive human rights violations. Moreover, even if dogmatism has practical consequences that are troubling, a defender of the value of knowledge and truth has a counterargument here. The typical epistemological approach involves abstracting away from the causal consequences of holding the beliefs in question, concerning itself more with intrinsic features of cognition, the kind reflected in talk of inquiry for its own sake. When we engage in inquiry for its own sake, successful results will partake of a kind of success that is independent of any causal contribution to well-being or other practical concerns. When epistemologists reflect on the nature of successful cognition and the extent to which an organism achieves it, the predominant approach has been to reflect on a kind of success that abstracts from the consequences of cognition, whether those consequences are practical, moral, religious, political, or social.

Given such an abstraction, a defender of the value of knowledge and truth can argue that even if Pyrrhonism is correct as a general approach to cognition, it fails to show that, from the abstract point of view of what is involved in inquiry for its own sake, knowledge and truth are not valuable. One of the factors to be considered in evaluating the plausibility of any view regarding the all-things-considered value of knowledge and truth is the

perspectival value of these things, such as the value they (appear to) have from the perspective of inquiry for its own sake.

Moreover, the argument for Pyrrhonism as the best view of the all-things-considered value of knowledge and belief is weak. To the extent that dogmatism itself has untoward consequences, the proper remedy is a sense of human fallibility, and only a highly questionable theory in which knowledge must be infallible could view skepticism as the only antidote to dogmatism.

Another threat arose in the latter half of the twentieth century, from those whom Bernard Williams in his last major philosophical work (2002) labeled “deniers” of the value of truth. Some of these deniers claim, in post-modernist spirit, that the ideals of truth and objectivity in inquiry are pretensions in service of other, baser motives. Problems for such denials of the value of truth arise when attempts are made to delineate accurately the nature of the pretensions in question and the lessons to be learned about the human condition from such investigation. Some, such as Richard Rorty (1989), have sought to espouse views while at the same time denying their accuracy, but such a position is not intellectually stable. The instability of the view is masked by the false dilemma involved in always capitalizing terms like “Truth” and “Reality” to gain purchase for the view that these concepts always and everywhere posit a metaphysical space hidden behind the pale of language or experience, yielding the claim that inquiry should aim at something weaker than truth, such as widest possible agreement (see Rorty 1998). As Williams points out, however, it makes little sense to value the number of converts to a view unless convincing them of the view has something to do with convincing them that the view is true. Put more generally, among the regulating ideas concerning truth is that there is an obvious logical equivalence between  $p$  and *it is true that  $p$* , so that to assert a claim is to represent that claim as being true, and no philosophical sleight of hand involving capitalization of terms or scare-quotes, to which such deniers are prone, undermines this central point about truth. The deniers may have useful and important critiques of pretensions to objectivity, but it is a fundamental principle of inquiry that claims and arguments that are self-refuting should be avoided.

## THE NATURE OF THE VALUE IN QUESTION

So there are three primary questions regarding the value of knowledge and truth. The first is whether knowledge and truth are valuable, all things considered. The second

question is whether they are valuable from the abstract point of view of what is involved in inquiry for its own sake. And the third question pertains to the issue of explanation, asking whether it is really knowledge that is valuable from this purely cognitive point of view, or something else instead.

The first question is a very large one, but a proper answer to it depends on answers to the second two questions, for if knowledge and truth do not pass scrutiny when considered from the purely cognitive point of view, then they have little to be said in their favor from an all-things-considered point of view. Furthermore, a negative answer to the third question would threaten the significance of a positive answer to the second question.

**THE VALUE OF TRUTH.** The major concerns involved in the third question are whether knowledge is more valuable than its parts and whether truth has anything to be said on its behalf over mere empirical adequacy. From a purely cognitive point of view, as William James (1956) noted, human beings are motivated by two primary concerns, a concern for not being duped and a concern for not missing out on something important. The first concern is relevant to the issue regarding whether truth has anything to be said on its behalf over mere empirical adequacy. If we adopt the literary device of a narrator commenting on various scenarios, we find something of an answer to this question. If one of the scenarios is the evil demon world and the other the actual world (as we suppose it to be), with the narrator being the very same person in each of these scenarios, the narrative will almost certainly treat the evil demon scenario as disturbing in comparison to the actual scenario, precisely because the narrator is being duped in the former but not in the latter. The most straightforward explanation of this response is that we find getting to the truth intrinsically valuable in virtue of our concern for not being duped.

The second concern above, the concern for not missing out on something important, raises a further problem, the problem of whether all truth is intrinsically valuable or only the important truths (see Ernest Sosa 2003). It is certainly true that we view some truths as simply unimportant, but that fact need not be taken to undermine the intrinsic value of truth, for it may be that our practical needs, goals, and interests interact with the intrinsic value of truth so that some truths are simply unimportant, all things considered, even though truth is still intrinsically valuable from a purely cognitive point of view, or from the point of view of inquiry for its own sake.

**THE VALUE OF KNOWLEDGE.** The value of truth raises the question of whether knowledge is more valuable than the sum of its parts; an affirmative answer to this question faces serious obstacles. Note first the variety of ways in which one might defend the value of knowledge. After seeing the above defense of the value of truth, an obvious response would be to argue that knowledge is intrinsically valuable, valuable independently of any value possessed by its parts, and more valuable intrinsically than any collection of its parts. It is instructive to note that such a maneuver is not as promising here as it is in the case of truth. On the one hand, when asked, “Why, from a purely cognitive point of view, do you value truth?” we are hard pressed to say anything informative at all, and this difficulty is an indication that we do not value truth on the basis of our valuing something else, but rather that we value it intrinsically. On the other hand, when asked, “Why, from a purely cognitive point of view, do you value knowledge?” we are inclined to answer. Our answer might be that we want to be correct, but not merely by accident, as happens when one has merely a true belief. The inclination to answer in ways such as this suggests that we value knowledge in a way that is different from the way in which we value truth, that even if truth is intrinsically valuable, knowledge is valuable because of the features that distinguish it from true belief.

What are these features? The traditional view is that knowledge is true belief that is justified, but the literature deriving from Edmund Gettier’s seminal paper of 1963 shows that no fallibilist view about justification can accept this account of knowledge. Fallibilism about justification is the view that justified false beliefs are possible, perhaps clarified in terms of the claim that no matter how good our evidence is for what we believe, we might still be wrong. Given this view, it turns out to be unavoidable that there could be cases of justified true belief that are not cases of knowledge. Hence another condition—a fourth condition—must be added.

*Justification and knowledge.* We should expect to find the value of knowledge, then, by examining the value of the additional elements of knowledge—justification and whatever fourth condition is needed. The standard conception of justification makes it difficult to use in a defense of the value of knowledge, however. The standard conception of justification is teleological: holding justified beliefs is the proper means to adopt when one’s goal is to get to the truth (and avoid error). If we think of means to a goal in terms of that which makes achieving the goal likely, the standard conception of justification amounts to the idea that justification is a property of a

belief in virtue of which that belief is objectively likely to be true.

A theory will need to say something different from the simple claim that justification is to be understood in terms of objective likelihood of truth, however, if it is to have any hope of providing a basis for explaining the value of knowledge over the value of its parts. Recall that the task is to explain the value of knowledge over that of true belief, so if an appeal to justification is to aid in this task, the theory of justification provided must support the idea that justified true belief is more valuable than mere true belief. It is not enough simply that justification is a valuable property for a belief to have, for that result would only show that justified belief is more valuable than unjustified belief, not that justified true belief is more valuable than true belief. Another way to put this point is as follows: It is necessary for justification to be valuable for it to play a role in explaining the value of knowledge, but its having such value is not by itself sufficient for it to play such a role.

The reason the value of justification is not sufficient is because of the swamping problem, as explained by Linda Zagzebski (1996), Richard Swinburne (2001), and Jonathan Kvanvig (2003). To see the problem, consider the following analogy. Suppose one wants to visit a nearby bookstore with a good philosophy section while visiting an unfamiliar city, and one searches the Internet to find a store. Two sites are generated, one titled “Bookstores with a good philosophy section” and another titled “Bookstores likely to have a good philosophy section.” Presumably, one will be more interested in the first than in the second, but the relevant point to note in our context is something different. Suppose one takes the time to construct the intersection of the two lists, resulting in a list of bookstores that both have and are likely to have a good philosophy section.

The point of the analogy is that it may be true that the first list is analogous to true belief, the second to justified belief, and the third to justified true belief. The swamping problem occurs in the bookstore example because the third list is no more valuable than the first when one’s interests are simply to visit a bookstore with a good philosophy section. The swamping problem in epistemology is simply that the value of justification is swamped by the value of truth when justification is conceived solely in terms of objective likelihood of truth, for the same reasons that a list of bookstores that both have and are likely to have a good philosophy section is no more valuable than a list of bookstores that have a good philosophy section.

There are two ways to develop a theory of justification that addresses the swamping problem and thereby provides an account of justification that is helpful in an attempt to explain the value of knowledge. The first is to deny that the means-ends relationship needs to be one of objective likelihood. According to this approach, sometimes the means we adopt are nothing more than wishes or hopes or prayers for achieving the goals we have, but they are means to the goal in question nonetheless. For examples of such, think of the plight of the hopeless suitor, flailing away in the dark trying to find some way of winning the heart of his beloved. He knows he has no clue how to succeed and he knows that everything he tries may not even increase his chances of success. Even if his efforts are not successful, however, they still constitute the means he has adopted to achieve the goal in question.

Just so, justification may be a means to the goal of having true beliefs without being conceived to yield objective likelihood of having such. According to such subjective approaches, there is value in pursuing the truth by whatever means or methods are best by one’s own lights, in full knowledge that these means or methods might have nothing more in their favor than hopes and wishes. Moreover, the value added by this property is not obviously swamped by the value of truth in the way that the property proposed by objective likelihood theorists is swamped, just as we value honesty and sincerity even when restricting our considerations to accurate reports. So one way of developing a theory of justification useful in the project of explaining the value of knowledge is to develop a subjective theory of justification.

The other way is to add further elements to the objective approaches so that the swamping problem is eliminated. One way to do so appeals to virtue epistemology, according to which knowledge is the product of the application of one’s intellectual virtues (see Greco 2003, Riggs 2002, and Sosa 2003). On a standard account of the intellectual virtues, a virtue is a stable trait of character that makes the beliefs it produces likely to be true. In this way, standard virtue theories adopt objective likelihood accounts of justification. They do not stop, however, with the idea that justification is simply objective likelihood of truth. They add that this objective likelihood of truth must also arise from the display of some laudable intellectual character. The true beliefs that result are not merely likely to be true, they also constitute *accomplishments* of the believer, so that having the true belief is something for which the believer is responsible. As a result, the cognizer deserves credit for having a true belief, and this credit is valuable in a way not explained by

the likelihood that the belief is true. For this reason, virtue approaches to justification have some hope of avoiding the swamping problem of providing an account of justification that is useful in the project of explaining the value of justification in terms greater than the value of its parts.

*The fourth condition for knowledge.* Were knowledge nothing more than justified true belief, these approaches to justification would give significant hope to the idea that knowledge is more valuable than its parts. Knowledge, however, is more than justified true belief; it is justified true belief where the connection between justification and truth is, in an appropriate way, nonaccidental. Various theories have been proposed regarding the appropriate kind of nonaccidentality that is required for knowledge, with the two most popular being the defeasibility theory and the relevant alternatives theory. There are serious worries that any approach to the fourth condition undermines the idea that knowledge is more valuable than its parts, and we can use these two theories to illustrate the difficulties.

The fundamental problem faced by all theories of the fourth condition is an insensitivity to the problem of the value of knowledge. In the *Meno*, Meno's response to Socrates's counterexample was to question why we prize knowledge more than true opinion and, indeed, whether there is any difference between the two. Meno's response reveals an important constraint on a theory of knowledge. To the extent that the theory focuses on the nature of knowledge at the expense of being able to account for the value of knowledge, it is suspect; and to the extent that a theory focuses on the issue of the value of knowledge at the expense of being able to account for the nature of knowledge, it is suspect as well.

The two major approaches to the fourth condition cited above provide excellent illustrations of how to err in each of these directions. Take first the relevant alternatives theory. On a relevant alternatives approach, the difference between knowledge and justified true belief is determined by whether one would be immune from error in alternatives to the actual situation. In perceptual cases, for example, suppose the surrounding area is littered with fake barns, but one happens to be looking at the only real barn in the area. Then in alternatives to the actual situation, one is not immune from error, for had one been looking at a fake barn, one would still have believed of it that it is a (real) barn.

This theory handles the fake barn case quite well, but it also risks implying global skepticism, if we consider the alternative situation in which Descartes's evil demon is

operative. In order to avoid this skeptical consequence, this approach introduces the qualifier "relevant," and holds that the evil demon scenario is not a relevant alternative to the actual situation. The pressing issue for this approach is to specify what makes a situation relevant, and here relevant alternatives theorists have had little to say. The most simplistic version of the view would simply rely on our intuitive understanding of the concept of relevance, claiming that no more precise theoretical specification is needed.

Such a theory is well suited to addressing the issue of the value of knowledge. Immunity from error is itself a good thing, and it would be hard to argue that one should prefer such immunity in *irrelevant* alternatives to immunity in *relevant* alternatives. Whether this value could withstand the scrutiny needed to provide a full and complete answer to the question of the value of knowledge would remain to be seen, but the theory provides some hope of such. It provides such hope by identifying a property with obvious evaluative dimensions, and in this way follows the strategy of addressing questions regarding the value of knowledge by identifying evaluative features of knowledge not present in mere true belief or even in justified true belief.

What this theory gains through the use of the concept of relevance in addressing the problem of the value of knowledge, however, it sacrifices in addressing the problem of the nature of knowledge. For without some clarification of the concept of relevance, this approach is a nonstarter for addressing the problem of the nature of knowledge. It is important to recognize explicitly the significance of the intuitive concept of relevance, however. For the evaluative nature of this concept gives one precisely what one would wish for when focusing on the question of the value of knowledge. It is unfortunate that the simplistic version of this approach has no similar hope of adequately addressing questions regarding the nature of knowledge.

The defeasibility approach begins from a starting point that appears attractive in the search for a solution to the problem of the value of knowledge as well. The starting point for such theories is that what distinguishes knowledge from mere justified true belief is the absence of defeaters—information that, if acquired, would undermine the justification in question. In the fake barn case above, the further (unknown) information is that the landscape is littered with fake barns that cannot be distinguished from real ones.

This starting point is attractive from the point of view of the problem of the value of knowledge, for it cites

a valuable property for a belief to have. It is valuable to have a belief whose justification cannot be undermined by learning any new information. The problem is that this starting point is inadequate, and to the credit of defeasibility theorists, they move beyond the simple relevant alternatives theory above by providing detailed and sophisticated accounts of precisely what unknown information undermines knowledge.

These accounts thus provide the detail needed in a serious effort to uncover the nature of knowledge, but the details of these accounts are completely insensitive to questions regarding the value of knowledge. The standard approach to developing the needed detail is to assemble a stable of examples, some of which involve knowledge and some of which do not, and attempt to find some distinguishing feature of the defeaters in cases of knowledge to use in refining the initial insight of the defeasibility theory. The result of this strategy is an approach that has little hope of providing a defeasibility condition that tracks any difference in value, and thus provides little hope in the attempt to explain the value of knowledge over that of its parts.

For example, consider one of the ways in which the simple defeasibility account is inadequate. Testimony by reliable persons often provides a defeater for what we would otherwise be justified in believing. Suppose we have visual evidence that a friend, Tom, left the library at 11 p.m. Our justification can be defeated if Tom's mother says that Tom has an identical twin that we did not know about who was in the library while Tom was at home fixing his mother's dishwasher. Whether it undermines our knowledge, however, depends on other factors such as who she reports this information to and what they know about her. It will not undermine our knowledge, for instance, if she fabricates the testimony to the police who are checking out a crime that occurred in the library, and the police have a large file of made-up stories from this woman in defense of Tom, who has a long criminal record, especially if the file contains precisely this concocted story, which the police have already checked in prior cases, discovering that Tom is an only child.

The simple defeasibility approach was attractive in the search for an explanation of the value of knowledge because it is valuable to have opinions that no further learning can undermine. Once we see cases such as the above, however, the defeasibility approach loses this attractive feature, for one can have knowledge even when further learning would rationally undermine one's opinion. In such cases, it is true that even more learning would restore one's original opinion, but there is little comfort to be found there, for the same will be true of any true

belief, since if one knows all there is to know about a given claim, one will believe it if and only if it is true.

Defeasibility theories have had considerable difficulty in finding a condition that properly distinguishes when defeaters undermine knowledge and when they do not. The problem created by such approaches for the problem of the value of knowledge, however, is the tortured and ad hoc way in which various complex conditions are proposed to do the job. In light of the labyrinthine complexity that such accounts of knowledge display, no optimism is justified that such conditions will track any value difference between satisfying those complex conditions and not satisfying them. It appears that the most warranted conclusion to draw is that the task of distinguishing cases of knowledge from cases of non-knowledge has been revealed to be so difficult that epistemologists make progress on the question of the nature of knowledge only by proposing conditions that undermine any explanation of the value of knowledge by appeal to those conditions.

## CONCLUSION

So the idea that truth is valuable on intrinsic grounds from a purely cognitive point of view may be defensible, but the same kind of defense of the value of knowledge is implausible. Instead, the more plausible approach tries to show that knowledge is valuable in virtue of its parts, but attempts along these lines founder on the admission that knowledge can be fallible. Such a result is compatible with truth and knowledge being valuable both from a purely cognitive point of view and from an all-things-considered point of view, but then knowledge will not have the type of value it is ordinarily assumed to have.

## KNOWLEDGE AND VAGUENESS

When anthropologists painstakingly identified the taxon of the skeleton that later became known as "Lucy's child,"

There was no eureka. There was no grand turning point. The evidence kept dribbling in, and through hard labor and some dogged thinking we *did* solve the puzzle, not through revelation but through a sort of absorption, just below the level of explicit consciousness. It was as if the truth had slowly seeped through our pores, until we had come know it without knowing that we did. So when the final, indisputable confirmation came, we hardly noticed the event. What had once been a mystery had become—in hindsight, mind you—obvious from the start (Johanson and James Shreeve 1989, p. 203).

Instead of there being a clear point at which the anthropologists knew that the specimen was *Homo habilis*, there was stratification: The researchers began from obvious ignorance, inched up to being borderline knowers, and eventually emerged as clear knowers.

The vagueness of knowledge has substantial implications. When skeptics took over Plato's Academy, they tried to prove that there can be no knowledge. Such a proof would ensure that everything is a clear negative case of "knowledge." *Knowledge* would be a perfectly precise term; a skeptic should think twice before complaining about the vagueness of knowledge! Typically, borderline cases are flanked by clear cases (Figure 1), so

FIGURE 1

the vagueness of "know" positively invites the inference that there is at least some knowledge.

The vagueness of knowledge also affects principles of epistemic logic such as the "KK thesis": If you know, then you know you know. If the KK thesis were true, the anthropologists would have known that they knew from the moment they knew the taxon of Lucy's child.

Given a naturalistic perspective on knowers, the vagueness of "know" should be expected. Human perceptual capacities and memory trail off in the patterns made famous by evolutionary iconography (Figure 2).

### 1. THE SORITES PARADOX

Only a vague term (e.g., *human*) can serve as the inductive predicate of a sorites argument:

Base Step: There are now humans.

Induction Step: If there were humans  $n$  years ago, then there were humans  $n - 1$  years ago.

Conclusion: There were humans five billion years ago.

Because the earth is only 4.6 billion years old, the conclusion is false. The base step is clearly true and the argument is classically valid. Therefore, people naturally suspect the induction step. However, they are unable to specify a value for  $n$  at which the generalization is false.

If vagueness is merely a kind of ignorance, there is no need to find a counterexample to the induction step. One can know a generalization is false even if one cannot pinpoint where it breaks down. Consider an anthropologist who doubts that all of the skeletal fragments in a bag belong to a single individual but cannot identify any pair of fragments as belonging to distinct specimens. When the anthropologist weighs the bag and learns there are more than enough fragments to constitute one skeleton, that is all that is needed to refute the generalization that all of the fragments come from a single individual.

In common usage, a borderline case is often simply one that cannot be settled at a given stage of inquiry. When an archeologist sorts stones, a few are obviously tools and most others are clearly just rocks. There will be another

FIGURE 2

group of stones whose status cannot be determined by unaided observation. These borderline cases are put under a field microscope. The three-way sorting begins afresh. Borderline cases that survive this second stage of inquiry may eventually wind up under an electron microscope.

Philosophers focus on the minority of borderline cases in which there is no prospect of resolution. How many years did the Middle Ages last? Is Israel a new state or an ancient state? Philosophers are at sea with these questions, and because people are unsure what would count as correctly answering these questions, their ignorance cannot be relativized to a set of resources.

Epistemicists insist there remains a crucial resemblance between these absolute borderline cases and relative borderline cases; they take all vagueness to be a form of ignorance. Epistemicists solve the sorites paradox by claiming that there is a hidden counterexample to the induction step. After all, they know the base step is true and the conclusion is false; classical logic then licenses the deduction that the induction step is false.

In classical logic, denying the induction step of the above sorites argument is equivalent to asserting there is a number  $n$  such that  $n$  years ago there was at least one human being but the year before that there were no human beings. So belief that there is a counterexample to the induction step is equivalent to the belief that there was a first human!

Incredulous anthropologists counter that nature does not draw a sharp line between humans and nonhumans. Speakers have not made up for the absence of sharp boundary by supplying an artificial one. Consequently, anyone who searches for the exact year humans appear on the evolutionary timeline is conceptually confused.

## 2. INFINITE REGRESSES

David Sanford (1975a) points out that if finite sequences do not need beginnings or endings, there are neglected

solutions to infinite regress problems. Consider the infinite regress of justification: A belief can only be justified by another justified belief. Justification cannot be achieved by reasoning in a circle. Nor can chains of justification be infinitely long. The skeptic concludes that no beliefs are justified. The foundationalist responds by conferring axiomatic status on some beliefs; axioms justify other beliefs without needing justification from other beliefs. The vagueness of “justified” suggests another solution to this infinite regress: Admit that the chain of justification is finite but deny it must terminate in an axiomatic belief.

Compare justification to motherhood. Each woman must have a mother. Her family tree cannot go back infinitely and cannot circle back on itself. Is one to conclude that some woman lacks a mother? Sanford instead appeals to the vagueness of “mother.” As one moves down her ancestral line, what counts as a mother eventually becomes less and less clear. After passing through a stretch of borderline cases, one arrives at ancestors who clearly lack a gender and therefore are clear nonmothers. Sanford says that an insistence that finite sequences have terminal points is an incarnation of the sorites paradox.

## 3. THE LOGICAL PREDICAMENT

Because the sorites argument is classically valid, David Sanford must espouse a deviant logic. Supplemental logics (modal logic, deontic logic, etc.) merely add theorems to the standard stock; they cannot subtract the sorites from the list of valid arguments. So Sanford must target classical logic, weakening it just enough to stop its validation of the sorites—without causing too much collateral damage. In standard fuzzy logic, almost all classical theorems are rejected—except for the special case in which the truth-values equal full truth or full falsehood (Machina 1976). Sanford (1975b) accepts degrees of truth but prefers to keep all classical theorems by rejecting the truth-functionality of the logical connectives. Other deviant logicians reject some classical inference rules. For instance, intuitionists closely associate proof with truth and so try to derail the sorites paradox by rejecting the validity of double-negation (Putnam 1983). Supervaluationists either reject inference rules such as contraposition and *reductio ad absurdum* or reject core semantic principles such as Tarski’s convention T (McGee and McLaughlin 1995).

These changes occur at the center of the human web of belief and so reverberate widely. Because knowledge implies truth, new questions are raised by the fuzzy logician’s talk of degrees of truth. For instance, can one know

a proposition that has a degree of truth less than one? The fuzzy logician wants to explain human ignorance of typical borderline cases and so is committed to saying that people are ignorant of propositions that are as close to being false as to being true. But what about propositions that are nearly true? Fuzzy logicians say that many propositions that appear to be clear truths merely have a high degree of truth. So if knowledge implies full truth, people know less than they seem to know.

#### 4. THE CREDIBILITY GAP

Knowledge does seem to imply full truth because knowledge implies belief and one can only believe what one considers to be fully true. “It is not fully true that the Black Skull is an australopithecine but I believe it is an australopithecine” is as hard on the ear as G. E. Moore’s paradoxical sentence “It is raining but I do not believe it” (Moore 1942, 543).

This credibility gap hinders efforts to moderate epistemicism. Intuitively, people’s wishy-washy attitude toward borderline cases seems like a reaction to the vagueness of these cases. But a subjectivist may reverse the relationship and say that the wishy-washy attitudes are what make propositions vague. If indeterminacy is a *projection* of human ambivalence, then people may hope to avoid the metaphysical burden of epistemicism. The epistemicist would be right in basing vagueness in the subject’s limitations but wrong in postulating sharp thresholds.

Crispin Wright (2001) says that  $x$  is a borderline case of  $F$ -ness if two parties can disagree about whether  $x$  is  $F$  without either party being guilty of a cognitive shortcoming. Each party knows all the relevant facts, each is a competent speaker, and each has reasoned well. Wright compares this faultless stalemate with the cultural variation that makes relativism popular among ethnographers.

Critics of Wright object that anyone who takes a position on a borderline statement is guilty of a cognitive shortcoming; they ought to be agnostic. If one thinks that same-sex civil unions are borderline cases of marriages, then one cannot believe that they are marriages.

Stephen Schiffer (1998) has suggested that people have a special attitude toward cases that they take to be borderline. “Vague partial belief” differs from the belief humans extend to precise propositions. It also differs from the degrees of belief that people associate with probability theory. The probability calculus instructs people to assign a higher probability to a disjunction than either of its contingent disjuncts. But when the disjuncts

are borderline cases, Schiffer only assigns the disjunction as much vague partial belief as he assigns the strongest disjunct.

This result (which echoes the fuzzy logician’s rule for calculating disjunctions) grates against the observation that hedging a claim can make it more assertible. One can know that Blaise Pascal died at thirty-nine but not be sure whether this counts as dying as a young man. However, one can confidently say that *either* Pascal died as a young man or as a man in middle age.

Supervaluationists have a simple explanation of why people do not believe borderline statements: they lack truth-values. Belief aims at truth, thus people cannot believe a statement that they believe to be borderline. However, this explanation overgeneralizes, for it does seem possible to have weak propositional attitudes (guessing, doubting, and suspecting) toward statements that one acknowledges to be borderline.

Supervaluationists also have trouble explaining why one can make a statement more credible by adding an *epistemic* hedge. If one believes linguistic indecision prevents “ten is a small number” from having a truth-value, then one cannot believe it may be true. Yet if ten clearly is a borderline case of a small number, then it is appropriate to shrug one’s shoulders and conclude “ten might be a small number and ten might not be a small number.” Indeed, prefixing any statement that is clearly borderline with “maybe” seems to make it clearly true.

Supervaluationists use truth-value gaps and the principle that knowledge implies truth to explain why humans are absolutely ignorant of borderline statements. God cannot know when a fetus becomes a human being because there is nothing to know.

Supervaluationists pride themselves on the modesty of their revision of classical logic. The workhorse of their adjustment is the notion of super-truth: A statement is super-true if and only if it comes out true under all admissible precisifications of the statement. For instance, “Either the specimen is a *Homo erectus* or an archaic *Homo Sapien*” is super-true because it comes out true regardless of how one precisifies *Homo erectus* and *archaic Homo sapien*.

Any statement that has the form of a classical tautology will be super-true even if it contains vague terms. So supervaluationists claim to preserve all the theorems of classical logic.

But can one believe a statement by virtue of its super-truth? Truth under all *disambiguations* is not enough. Suppose a person says “bachelors are mammals”

and it is not clear whether that person is referring to unmarried men or to college graduates or to just any young male mammal. One knows the statement expresses a truth but does not know which truth it expresses. Ambiguous statements are not objects of knowledge.

But vague statements are objects of knowledge. People know “the number of men is either an even number or an odd number” even though the vagueness of “man” makes it impossible to count the number of men. Supervaluationists have trouble accepting asymmetries between vagueness and ambiguity. They characterize vagueness in semantic terms rather than epistemic terms, so supervaluationism looks more like a logic of ambiguity (Lewis 1982).

## 5. HIGHER ORDER VAGUENESS

In *Purity and Danger* Mary Douglas conjectures that the bearers of taboos are borderline cases (moles, eels, twilight, and so on). She interprets rituals of purification as attempts to reclassify doubtful cases (as when hermaphrodites are declared men through a rite of passage). Assessment of Douglas’s hypothesis is hindered by the vagueness of “borderline case.”

Borderline cases of “borderline case” are normal with vague terms. In addition to there being borderline cases of “human,” there are borderline cases of “borderline human.” So in addition to first order vagueness there is second order vagueness, third order vagueness, and so on, apparently ad infinitum.

Higher order vagueness is a problem for deviant logicians because they employ classical logic and set theory in the metalanguages they use to describe vague terms. This classical medium forces them to represent the transition from clear to borderline cases as a sharp threshold. For instance, supervaluationist semantics implies that there is a first point at which “*x* is a human” is true. So instead of having the epistemicist’s sharp threshold between truth and falsehood, the supervaluationist has a sharp threshold between truth and absence of truth. Similarly, the fuzzy logician has sharp thresholds between each degree of truth, and can only approximate vagueness by using a large quantity of discrete micro-transitions. The fuzzy logician’s representation of vagueness is like a dot matrix printer’s representation of gray—a black and white affair when examined close up.

What originally bothered philosophers were *sharp thresholds*, not sharp thresholds *between truth and falsehood*. Thus epistemicists advertise themselves as just self-consciously biting a bullet that others gnaw absentmindedly.

## 6. EXPLAINING THE IGNORANCE

Recent epistemicists are careful to endorse the principle that inquiry into borderline cases is futile. That is why they stress that borderline statements are unknowable. But if these statements have truth-values, why can’t they be known? One response is to challenge the presumption in favor of knowability—to portray ignorance as a natural state in need of no explanation.

However, Timothy Williamson (1994) directly answers the question of why borderline statements cannot be known. He traces the unknowability of borderline statements to the knower’s need for a margin for error. When at a stadium, one can know there are about ten thousand people. But one cannot know there are exactly ten thousand, for a person cannot reliably discriminate between there being ten thousand and there being ten thousand and one. Given that “human” has the sort of precise threshold epistemicists allege, anyone who happened to correctly believe that humans originated *n* years ago, would have to be right by luck. For all this person knows, the origin could have been a year earlier.

Williamson believes that thresholds for vague predicates are determined by the psychology, social conditions, and environment of the speech community. These conditions are too complicated to allow humans to ascertain the threshold for vague terms.

The margin for error principle yields different limits for different kinds of knowers. For much of the history of *Homo sapiens* there were other hominids who had different cognitive capacities. Williamson’s theory does not preclude these hominids from knowing the threshold of some vague terms. Some of what is chaotic to humans may be predictable to these hominids. Williamson is committed to the relativity of all borderline cases. Supervaluationists claim an advantage over Williamson insofar as they neatly model absolute borderline cases.

Roy Sorensen (2001) has speculated that an epistemicist can match the neatness of the supervaluationists by using truth-maker gaps instead of truth-value gaps. A truth-maker is what makes a proposition true. For instance, “Humans and chimpanzees had a common ancestor seven million years ago” is made true by a Miocene primate who had as descendants both Noam Chomsky and Nim Chimpsky. One learns the truth-value of propositions only by becoming appropriately related to their truth-makers. Propositions that lack truth-makers have truth-values that are not anchored to any piece of reality. This objective indeterminacy makes the propositions absolutely unknowable.

## 7. VAGUENESS AND EPISTEMIC LOGIC

If the relationship between knowledge and borderline cases is orderly, epistemicists can offer a logic of vagueness as a branch of epistemic logic. For instance, Timothy Williamson elaborates his “logic of clarity” in a way that makes it isomorphic to supervaluationism. The basic idea is that a statement is definitely true if it comes out true “under all sharp interpretations of the language indiscriminable from the right one” (Williamson 1999, p. 128). This mirrors the supervaluationist’s principle that a statement is definitely true if it comes out true under all admissible completions of the language.

Epistemicists are divided on how closely vagueness is bound up with borderline cases. Everybody agrees that a vague term need not have actual borderline cases. Possible borderline cases are sufficient. But what about borderline cases that are merely epistemically possible? Perhaps the mere threat of an objective borderline case can be enough to make a predicate vague (Sorensen 2001). After all, if the threat cannot be exposed as false, then there will be irremediable linguistic ignorance without borderline cases. One would be able to embed the predicate in a sorites argument and bedevil people with doubts about termination points.

## KNOWLEDGE ARGUMENT

The definitive statement of the knowledge argument was formulated by Frank Jackson in a paper titled “Epiphenomenal Qualia” that appeared in the *Philosophical Quarterly* in 1982. Arguments in the same spirit had appeared earlier (Broad 1925, Robinson 1982), but Jackson’s argument is most often compared with Thomas Nagel’s argument in “What Is It Like to Be a Bat?” (1974). Jackson, however, takes pains to distinguish his argument from Nagel’s. This entry will follow standard practice in focusing on Jackson’s argument, though it also describes the main points of alleged similarity and dissimilarity between these two arguments.

The knowledge argument targets physicalism about the mind, which claims that, as Jackson puts it in a follow-up article, “the actual world ... is entirely physical” (1986, p. 281). The argument provided one of the chief sources of doubt about physicalism in the late twentieth century, and continues to shape discussion of the mind-body problem into the twenty-first. It is unclear whether the argument converted many to dualism; still, most readers found the argument’s core thought experiment highly compelling. Physicalists thus faced the challenge of identifying an error in the argument. The potency of the knowledge argument is clear because while all materialists reject its conclusion, there is little agreement among them as to how, precisely, its reasoning is flawed.

### THE ARGUMENT

Jackson’s original argument is disarmingly brief. He invites the reader to imagine the following scenario: Mary, a brilliant neuroscientist, has spent her entire life in a room in which the only visible colors are black and white. Partly through the use of a black-and-white television monitor, Mary comes to know all of the physical facts about color vision. These facts include the nature of causal interactions between the surface reflectance properties of objects, wavelengths of light, and retinal stimulation. Jackson then asks: “What will happen when Mary is released from her black and white room or is given a

color television monitor? Will she *learn* anything or not?” He answers: “It seems just obvious that she will learn something about the world and our visual experience of it” (Jackson 1982, p. 130). He thinks that when Mary finally leaves the room and, for the first time, gazes upon an object that is red (and that she knows to be red), she learns *what it’s like* to see red. Jackson concludes that, because physicalism requires that all facts are physical facts, physicalism is false.

Jackson’s conclusion is a dualism of properties, rather than of substances; and this is all that his argument warrants. For a difference in properties—between the property *instantiating neurophysiological state N*, and the property *instantiating qualitative state Q*, say—suffices for a difference in corresponding facts.

A formalization of the argument will be useful.

(1) While in the black-and-white room, Mary knows all of the physical facts about color experience.

(2) Mary learns something about color experience upon her release.

(3) If Mary learns something about color experience upon her release, she does not know all of the facts about color experience while in the room.

(4) Mary does not know all of the facts about color experience while in the room (from 2 and 3).

(5) There are facts about color experience that are not physical facts (from 1 and 4).

(6) If physicalism is true, then all facts are physical facts.

Therefore,

(7) Physicalism is false (from 5 and 6).

As mentioned above, Jackson distinguishes this argument from Nagel’s 1974 argument. Nagel had argued that no amount of physical information about bats—including knowledge of their neurophysiological, behavioral, and evolutionary features—could allow us to grasp the experiential aspect of using echolocation; that is, to know what it’s like to be a bat. According to Jackson, these arguments differ in two ways. First, he claims that his argument concerns knowledge of a general property of experience, what it’s like to see red, whereas Nagel’s argument concerns knowledge of a property specific to an individual; that is, what it’s like to be a (particular) bat. But to some, this difference has seemed at most a quirk of exposition: for Nagel’s argument does draw into question whether we can know a general property of experience, namely, what it’s like to use echolocation. However, oth-

ers—including Jackson himself—have claimed that whereas Jackson’s argument specifically targets the contrast between the phenomenal and the physical, Nagel’s argument instead targets the contrast between the subjective and the objective.

The second point of contrast that Jackson draws is this: Nagel’s argument simply shows that humans cannot imagine what it’s like to use echolocation, and this limit to our imaginative powers is irrelevant to the issue of physicalism. Whether Nagel’s argument rests on this issue about imaginability, or whether it would remain intact when using an experience that is within the normal course of human experience (as Jackson’s does), is largely a question of interpretation. But the point about imaginability brings out an important and sometimes overlooked feature of Jackson’s argument: that nothing in the argument excludes the possibility that Mary, perhaps through an exercise of imagination or as the result of taking a hallucinogen, undergoes an experience while in the room that is, in fact, a *seeing red* experience. Jackson’s point remains so long as Mary is unable to determine that the experience is a *seeing red* experience as opposed to, say, a *seeing green* experience. This brings out the epistemic character of the argument. Jackson’s argument requires only that Mary cannot *deduce* that a certain experience is the sort of experience her subjects undergo when seeing a ripe tomato (say). Upon leaving the room, Mary has the opportunity to *correlate* these, by gazing at a tomato herself. (She could, of course, correlate them while inside the room, by scanning her own brain while she is undergoing the *seeing red* experience. In the context of the argument, having the opportunity to make this correlation is tantamount to leaving the room.)

## OBJECTIONS TO THE ARGUMENT

This entry now turns to the four most influential types of objection to the argument. The first is simply to deny the conjunction of premises (1) and (2). On this view, Mary does not know all of the physical facts unless she knows what it’s like to see red. Daniel Dennett (1991) takes this approach, arguing that we cannot truly conceive knowing all of the relevant physical facts. This limitation explains why it seems that Mary learns something upon her release; but, Dennett maintains, if (1) is true, then (2) is false. In response, defenders of the knowledge argument have pointed out that the argument requires only that we understand the basic kind of knowledge that Mary has while in the room, not that we can mentally rehearse each bit of information she possesses. Because we do have a grasp of the sort of physical facts she knows, our powers

of conceiving are strong enough to evaluate the possibility that (1) and (2) are true simultaneously.

The next two objections deny premise (3). Churchland (1985) describes what Mary gains upon her release as a kind of *knowledge by acquaintance* of what it's like to see red; that is, as nonpropositional knowledge of this fact. Using this analysis of the case, he argues that a parallel argument would condemn dualism as well, because Mary would lack such knowledge by acquaintance even if she had exhaustive propositional knowledge about the nonphysical. Jackson (1986) responds that these are not on a par, for one could know all of the physical facts about seeing red without knowing what it's like, but one could not know all of the facts (physical and nonphysical) about seeing red without knowing what it's like. This may seem question-begging, but it has seemed highly intuitive to many philosophers, and hence this second avenue of objection has attracted relatively few proponents. (But see Earl Conee 1994 for a more developed version of the acquaintance analysis.)

Another objection that denies premise (3) claims that what Mary gains upon leaving the room is an ability, rather than knowledge of a fact. This objection originated in Laurence Nemirow's review of Nagel's argument (1980), and is defended by David Lewis (1988). On this *ability* approach to defusing the argument, when she finally sees something red, Mary learns how to remember, recognize, and/or imagine a *seeing red* experience. The fact that experience is required for such abilities carries no antiphysicalist consequences; after all, exhaustive propositional knowledge does not generally guarantee that one possesses the relevant ability. If it did, professional baseball teams would be staffed by physicists, who can master all of the relevant facts about how to hit a curve ball.

While the ability approach remains influential, it does face difficult challenges. One challenge is to specify an ability that is gained when, and only when, Mary learns what it's like to see red. At the moment of her grasping this, she is not yet able to remember what it's like, for the moment has not passed; and if she has a poor imagination, experience may not enable her to imagine what it's like. (For responses along these lines, see Conee 1994 and Torin Alter 1998.) Arguably, the best candidate for what Mary gains is the ability to recognize *seeing red* experiences. But the ability analysis may be mistaken even if this recognitional ability is perfectly correlated with knowing what it's like to see red. For, as Brie Gertler (1999) argues, it seems plausible that Mary is able to recognize a *seeing red* experience *because* she knows what it's

like, where *because* is used in an explanatory sense. If knowing what it's like explains the recognitional ability, then it does not reduce to that ability.

The fourth and most widely accepted type of objection to the knowledge argument rejects premise (6). It claims that our ways of representing reality may be more fine-grained than the reality we represent, and what Mary gains is simply a new way to represent a portion of reality that was already known to her. (There are two competing ways to use *fact* in this context. One is to read *fact* as inheriting the fineness of grain that our representations possess; it is this reading that has been used in saying that this objection targets premise (6). The second reading uses *fact* as less fine-grained than our representations. On that reading, the current objection would instead reject premise (3), claiming that Mary didn't learn any new facts but only encountered old facts under a new guise or mode of presentation. The difference here is purely verbal, and this entry will continue to use *fact* in the former sense.)

This sort of objection was present in earlier papers (including Terence Horgan 1984 and Michael Tye 1986), but is usually associated with Brian Loar, who provided a nuanced version of it in 1990. Loar argues that a single property may be the referent of distinct concepts. In particular, a property that Mary knew as *instantiating neurophysiological state N* may be identical to the property *instantiating qualitative state Q*, even if knowledge that a state falls under the former concept does not generate knowledge that it falls under the latter. Thus, Mary's ignorance can be attributed to a distinction in concepts that does not imply any distinction in properties.

More generally, this line of response to the knowledge argument construes the change in Mary as purely epistemic, and denies that her epistemic advance, upon leaving the room, reflects any grasp of a hitherto unknown ontological feature of the world. As such, it represents a more general, highly influential position about the mind-body problem: The apparent disparity between physical and phenomenal features of the world (called *the explanatory gap* after Joseph Levine "1983") is purely epistemic, and not ontological.

This position belongs to a more general outlook known as *a posteriori physicalism*. According to *a posteriori* physicalists, antiphysicalist arguments that are based on thought experiments show, at most, that physicalism is not an *a priori* truth; but as Saul Kripke (1980) demonstrated, some identities are *a posteriori* (yet necessarily true). Strikingly, Kripke himself rejects *a posteriori* physicalism and claims that the distinctive way in which phenomenal concepts operate rules out the possibility of *a*

*posteriori* identities between phenomenal and physical (or functional) properties. In a paper co-written with David Chalmers, Jackson also objects to a *posteriori* physicalism. According to Chalmers and Jackson (2001), the approach used by a *posteriori* physicalists presumes that there is a deep schism between concepts and ontology, a schism that would undercut the justification for uncontroversial identity statements.

Despite his continuing opposition to a *posteriori* physicalism, Jackson now rejects the knowledge argument (Jackson 2003). He contends that phenomenal knowledge is deducible, in principle, from physical knowledge, even if we may be unable to perform the deduction. Jackson's turnabout is based on his acceptance of representationalism, which claims that the phenomenal character of a state is exhausted by its representational content. For instance, suppose that one of Mary's subjects, Joe, gazes at a ripe tomato. Representationalists maintain that the visual phenomenal quality of Joe's experience is fully captured by the fact that his state represents *there is something round and red before me*. (Specific representational contents will be much more detailed, of course.) Because Mary can, in principle, know the representational contents of Joe's states before her release, she can in principle know all that there is to know about what it is like to see red.

## OVERALL ASSESSMENT

The knowledge argument is an argument against physicalism. Yet its importance stems as much from the richness and variety of the responses inspired by its provocative reasoning as from its conclusion. Discussion of the argument has profoundly affected debate on a range of issues, including: differences between propositional knowledge and ability, the relation between identity and deducibility, and the special features of phenomenal knowledge. While the majority of philosophers ultimately reject the argument, a vocal minority accepts it as sound.

## KNOWLEDGE IN INDIAN PHILOSOPHY

Almost all the philosophical texts in classical India were written in Sanskrit. How does one say *knowledge* in Sanskrit? And what do the Sanskrit terms that may be translated by the English word *knowledge* mean exactly? There are no simple answers to these questions.

In Western philosophy truth and falsity are usually ascribed to statements, propositions, or beliefs. In the Indian tradition truth and falsity are ascribed to a cogni-

tion or an awareness (the most common term is *jñāna*, but there are a relatively large number of synonyms, or quasi synonyms, such as *vijñāna*, *buddhi*, *dhī* and *citta*). The word *jñāna* is derived from the root *jñā*, which is etymologically related to the English word *know*. Nevertheless, the rendering of *jñāna* as knowledge is generally avoided because *jñāna* can be true or false, whereas false knowledge or wrong knowledge seems like a contradiction in terms (at least in English). Furthermore, *jñāna* is a particular and momentary event, whereas *knowledge* often refers to a general and lasting acquaintance with facts. Furthermore, knowledge is, or may be, an abstract entity that is shared by many persons; *jñāna* is always individual and belongs to a single person. Finally, *knowledge*, unlike *jñāna*, is a collective term and can only be used in the singular. A person has many *jñānas*, but not many *knowledges*.

The different ontologies of the various traditions of Indian philosophy necessitate different notions of *jñāna*. According to some Brahminical schools, *jñāna* is a momentary property of the eternal individual soul (*ātman*). The relationship between *jñāna* and soul is the relationship between quality and substance. It is the same relation that occurs between a color and the material substance like a pot in which it inheres. In contrast, the Buddhists reject the idea of substance in general and of a permanent soul or self in particular. According to them an awareness (*jñāna*) is a primitive (nonderivative) element of existence (*dharma*) that depends only on its causes and conditions (e.g., sense, object, and previous mental factors), not on any substrate such as a permanent soul. The Sāṃkhya and Yoga are unique in the Brahminical tradition in claiming that the cognitive and psychological processes occur in the realm of matter and have no direct contact with the conscious soul, which is distinct from them and completely passive (for more details, see Chakravarti 1975, pp. 171–196). Finally, according to the materialists (Cārvāka or Lokāyata), an awareness, or consciousness, arises from the combination of the material elements earth, water, fire, and wind when they evolve into body, sense, and object, just as the power of intoxication arises when certain substances ferment (Namai 1976, Franco 1997, pp. 98–99).

Knowledge in general as referring to an organized body of knowledge, or even a science, is usually called *veda* or *vidyā* (words that are cognate with Latin *videre* and the English *to wit*). When the word *veda* is mentioned without further qualification, it always refers to the four collections of texts known as Ṛgveda, Yajurveda, Sāmaveda, and Atharvaveda. These contain *the* knowledge, the knowledge par excellence. The Vedas are the primary scriptures of Brah-

manism and Hinduism. According to Brahminical orthodoxy they are neither of human nor Godly origin, for they are eternal and infallible. The text of the Vedas was revealed (not created) by omniscient Gods such as Brahma, or directly heard by inspired seers (Rishis) of old. Various enumerations and classifications of systematic knowledge, or sciences, have been transmitted; perhaps the most common ones refer to fourteen or eighteen locations of knowledge (*vidyāśtāna*): the four Vedas and the six auxiliary sciences to the Vedic texts (the sciences of articulation or phonology, prosody, grammar, etymology, astronomy/astrology, and ritual/ceremony), religious and social law (*dharmaśāstra*), collections of ancient myths (*purāṇa*), hermeneutics (*mīmāṃsā*), and dialectics (*tarka*); the eightfold enumeration adds medicine (*āyurveda*), archery or the science of weapons in general (*dhanurveda*), and *arthaśāstra*, which includes politics and economy.

These lists do not exhaust all the sciences known in ancient India, but they point to an attempt at an exhaustive classification of human cultural practices (Pollock 1985, p. 502). Sheldon Pollock, who examined the notion of *sāstra* in classical India, points out that virtually every human activity had been codified into a science (or a theory, as he renders the word *śāstra*), for instance, cookery, erotics (*kāmaśāstra*), thievery (*cauraśāstra*), agriculture, mathematics, logic, ascetic renunciation, and spiritual liberation. As a rule (there are notable exceptions), the various sciences have not been discovered by their practitioners. Rather, all practice is said to be derived from previously existing knowledge. Science itself is primordial; it is not accumulative, and can only decrease with time.

In Buddhist texts (both in India and Tibet) one encounters a list of five places or locations of knowledge (*vidyāsthānas*) that are to be cultivated by the Bodhisattva on his way to enlightenment. The first of these, the inner science or the own science (*adhyātmavidyā*), is specific to Buddhists, the other four—the science of logical reasons, grammar, medicine, and arts and crafts—are external and considered common to Buddhist and non-Buddhists (Seyfort Ruegg 1995, pp. 9–10). However, the status of the science of reasons, that is, philosophy/dialectics/logic, was ambiguous. Although its position following the inner science clearly implies that it is an external (or non-Buddhist) science, it was sometimes considered to be part of the Buddhist teachings. The science of logical reasons could be assimilated either to *tarka*, dialectics, which have nothing particularly Buddhist about them, or it could be understood as the science of the means of knowledge (*pramāṇa*), as expounded by Dharmakīrti (seventh century) and his followers that was closely associated to the

understanding and interpretation of the Buddhist teachings (Seyfort Ruegg 1995, p. 105). Deliberation and reasoning on the Buddha's teaching were widely perceived to be necessary steps before meditation. Traditionally, the study of the Buddhist scriptures was divided into three steps: listening to the Buddha's words, reflecting on them, and meditating on them.

However, another term that is often used to convey the idea of knowledge is *kalā*, sometimes translated by "art and craft," refers to both "knowledge that" and "knowledge how." There are long lists of the various *kalās* (also called *śilpas*), some of them enumerating sixty-four, some seventy-eight, some more than ninety types. A typical list would include the knowledges of writing, calculation, sculpting, painting, dancing, singing, playing on musical instruments, gambling, speaking courteously, various games, preparing drinks, preparing perfumes, composing poems in various meters, divination, poisons and antidotes, the movement of heavenly bodies, training horses and elephants, archery, and various forms of fighting.

However, these terms for knowledge are not extensively treated in Indian philosophical texts, and except for the four Vedas, do not play an important role in Indian theories of knowledge. For Indian philosophers are not so much concerned with the nature of knowledge as such, but with the means of knowledge (*pramāṇa*).

## PRAMĀṆA

To the question "how can one know something?" all Indian philosophers would answer unanimously: by having a means of knowledge. This answer may sound almost tautological and no two significant philosophers would understand the term in exactly the same manner. Nevertheless, the term *pramāṇa* played a crucial role in structuring the Indian epistemologies. It is around this concept, its definitions, and its varieties that Indian philosophy developed in its most dynamic period (roughly from the fifth to the twelfth century). The most important means of knowledge are sense perception (*pratyakṣa*), inference (*anumāna*), and verbal communication (*śabda*), under which sacred writings such as the Vedas or the teaching of the Buddha are subsumed.

What are the means of knowledge (*pramāṇa*)?

The number of means of knowledge that are accepted by the different schools of thought varies strongly. Madhyamaka Buddhists like Nāgārjuna, skeptics like Jayarāsi (Franco 1994), and monists of the Advaita-Vedānta tradition like Śrīharṣa, all of whom deny the possibility of knowledge, obviously accept no means of knowledge to be

reliable (Matilal 1977). All other schools admit that sense perception is a means of knowledge. The materialist school (Lokāyata) is distinguished from other schools by its claim that only sense perception is valid. The Vaiśeṣikas and the Buddhists after Dignāga (fifth century) admit two means of knowledge, namely, perception and inference. The Sāṃkhyas admit verbal communication by a trustworthy person (*āptavacana*) besides these two; Buddhist philosophers before Dignāga, for example, Vasubandhu, also admit verbal communication to be a means of knowledge. Philosophers of the Nyāya tradition, with the notable exception of Bhāsarvajña (ninth century), also admit analogy (*upamāna*) as a fourth means of knowledge. The same position was held by certain Buddhists (Franco 2001). The Prābhākara Mīmāṃsakas accept five means of knowledge: the previously mentioned four and presumption (*arthāpatti*). The Bhāṭṭa Mīmāṃsakas and Advaita-Vedāntins admit six means of knowledge: the previously mentioned five and absence (*abhāva*) or nonperception (*anupalabdhi*). In nonphilosophical texts one also encounters inclusion (*sambhava*) and tradition (*aitihya*) as means of knowledge. Since inference and verbal communication are dealt with in separate entries, this entry will focus mainly on a discussion of perception.

## PERCEPTION AND SENSES

*Perception* here refers primarily to sense perception. Indeed, the Sanskrit word that is usually rendered by *perception* is *pratyakṣa*; it contains the semantic element—*akṣa*—which means "eye." However, in some cases such as mental perception of feelings or the extrasensory perception of Yogis, the senses play no role in its arising. Perception is usually said to arise from sense and object. In this connection one has to emphasize the distinction between sense (or sense-faculty) and sense organ. The senses are not identical with the bodily organs to which they are associated. It is an extremely common mistake in Western publications to refer to the senses of seeing, hearing, smelling, touching, and tasting as eyes, ears, nose, skin, and tongue. Indian philosophers, however, clearly distinguish between them.

Thus, according to Nyāya the sense of sight is not the eye, but an invisible ray of light that rests on the pupil of the eye and goes out to reach the object. The sense of hearing is not the ear, but a part of space-ether (*ākāśa*) that is enclosed in the ear. The sense of taste is not the tongue, but a watery substance in the form of half-moon that is spread at the front of the tongue. The sense of smell is a substance made of earth and is found inside the nose; its base is usually called *nāsā*—a cognate of nose—

but sometimes also *tripuṇīkā*, that is, “the three cavities,” or “the triple cavity,” which seems to indicate that its base is the root of the nose. The sense of touch, which is sometimes interpreted as a sense of temperature, is also found inside and throughout the body, not only on the skin.

Already in the early philosophy of nature, the senses were considered to be material. Each sense—except for the auditory—was composed of the four material elements (earth, water, fire, and wind). Their special ability to grasp a certain elemental quality was explained as being due to their composition. The gustatory sense consists mainly of water, and it possesses the quality to be grasped, namely, flavor (*VS* 8.16–17). Although the element earth also possesses flavor, this quality is not predominant in it. The elemental constitution of the senses is based on the principle that “similar perceives similar.” The Nyāya, Vaiśeṣika, and the Mīmāṃsā accepted the so-called accumulation theory of qualities in elements.

Except for hearing, the senses are made of special invisible atoms. Therefore, they cannot perceive themselves and can only be inferred: From the fact that one has a visual awareness, one infers that one has a sense of sight. According to the Buddhists the senses are made of a special subtle and transparent matter (*bhūtaprasāda*); the transparency of this matter is used to explain both its invisibility and its receptivity to other forms. Unlike normal matter, the subtle matter of which the senses are made does not obstruct other matter. When Indian philosophers write about the senses, they think above all about sight. The sense of sight is often used as a model for all other senses; hearing is treated cursorily, the other senses are hardly ever discussed.

## PERCEPTION AND CONTACT

There was a strong debate that lasted for centuries between Buddhists and Naiyāyikas on the question of whether the sense and the object must be in contact to produce sense perception. The debate concerned only the senses of seeing and hearing (for everyone agreed that the other senses must be in contact with their objects). The Naiyāyikas and the Mīmāṃsakas maintained that all senses must be in contact with their objects to perceive them. In response to the Buddhist objection that sight perceives objects at a distance and objects that are larger in size than the sense itself, the Naiyāyikas postulated an invisible ray of light that goes from the eye and enters in contact with the object. This ray of light has a broad tip so that it can be in contact with large objects. It is in this context that certain optical theories were developed (Preisendanz 1989).

## PERCEPTION AND THE CRITERION OF TRUTH

For a general discussion of truth and error, notably of false inferences, see the entry “Truth and Falsity in Indian Philosophy.” The problem of truth is addressed here only in respect to perception. The earliest discussion on the criterion of truth can be found in a short passage of an anonymous Mīmāṃsā commentary that is now lost except in quotations and references in later sources that refer to its author simply as “The Commentator” (*vṛttikāra*) (Frauwallner 1968, pp. 107–111). It may seem odd that a Mīmāṃsā commentary that deals with Vedic exegesis should contain digressions on perception and related epistemological problems. Indeed, the rationale for the treatment of perception in Mīmāṃsā writings was originally a negative one: the rejection of sense perception as a means for the apprehension of the *dharma*, understood here as Vedic injunctions (*MS* 1.1.4).

According to the Commentator, “true perception is the arising of awareness when the senses of a man are in contact with precisely that which the awareness has for its object” (*SBh* 26.3–4). In other words, when the internal object that appears in the awareness and the external object that is in contact with the senses are identical, the resulting awareness is perception. This is, however, only a general definition. How can one know whether a specific awareness has arisen when the senses are in contact with the same object that appears in the awareness, or whether they were in contact with a different object? One may have an awareness of silver, but how is one to know whether the senses are in contact with silver, or with a glittering conch shell that produces an illusion of silver? The Commentator answers that a sublating awareness (*bādhaka-jñāna*) arises in respect to a false awareness and asserts its falsity, “That was not silver, the awareness was false.” However, the problem with sublation (*bādhā*) as a criterion of truth is that the sublating awareness arises later, sometimes much later, than the false awareness. How does one know when an awareness is true or false at the time it arises? At that moment there is no difference whatsoever between true and false awarenesses, for the person who mistakes a conch shell for a piece of silver also thinks, “My sense of sight is in contact with silver.”

The Commentator suggests that when the causal complex that produces the awareness is disturbed, the awareness is false; otherwise it is true. For instance, when the mind is disturbed by hunger, when the sense of sight is disturbed by an illness, or when the external object is too subtle, the awareness is false; when the causal complex is not disturbed, the awareness that arises from it is

true. By this assertion the Commentator makes the true awarenesses the normal ones, those people usually have, and errors are considered to be an exception. In other words, there is nothing inherently wrong in the cognitive process itself. However, the assertion that a true awareness is produced by undisturbed causes tells one what happens, but not when it happens. That a particular awareness has arisen from undisturbed causes remains to be proved for every single case. The Commentator maintains that if one earnestly searches and does not find any fault with the causal complex, then, because there is no proof to the contrary, we should think (*manyemahi*) that the awareness is true.

Later Mīmāṃsakas like Kumārila (seventh century) had to deal with problems that the Commentator had left open. For instance, in certain cases one is not in a position to rectify an erroneous awareness (*ŚV, Vṛttikāra-grantha* 23). A certain illness of the eye distorts vision in such a way that one sees a double moon. In such cases the mistaken person learns in his or her communication with other people that there is only one moon in the sky. Kumārila also had to deal also with errors that are immanent to the cognitive process. Such errors would render all everyday awarenesses, even those that are usually considered true, essentially erroneous. For instance, according to the Buddhists, every empirical awareness involves a conceptual construction. Empirical awarenesses have wholes (*avayavin*) and universals (*jāti*) as their objects, but these have no correspondence in reality. Even a simple awareness such as “this is a cow” contains at least two parts. The part *this* refers to some concrete individual, the part *cow* to a universal “bovinity” that, at least according to the Indian realists, is a single eternal entity present in all cows and is responsible for the fact that a great number of different individuals are all called cow.

The Buddhists have adduced powerful arguments against the existence of such universals. For instance, the universal bovinity cannot be present entirely in one individual cow, because if this were the case, it would not be able to reside in other cows. Nor can it be partly present in one cow, because it has no parts. Thus, all empirical awarenesses are false because they involve conceptual constructions, and conceptual constructions are faulty because they involve incoherent notions such as that of a universal. Kumārila’s response to such objections was to refuse a philosophical engagement. No matter what arguments the Buddhists may raise: If everybody invariably has the awareness in respect to a certain individual, “this is a cow,” then such awareness cannot be sublated, for it is more powerful than the other awareness that has found fault in it.

The concept of sublation may seem to presuppose a coherence theory of truth, in which truth is defined by relations between statements (or in the Indian case, between awarenesses), not in terms of relations between statements and reality, as is the case in a correspondence theory of truth. However, in general Indian philosophers always seem to presuppose a correspondence theory of truth. Even though only an awareness can sublimate, or assert the falsity of another awareness, this is possible only because the sublating awareness corresponds to reality and the sublated awareness does not. The direct relationship between the two awarenesses remained problematic, and in the final analysis unexplained. To the question of how an awareness that arises later can apprehend the inexistence of an object of an earlier awareness Jayanta, a Nyāya philosopher of the ninth century, simply replies, “What [can] we do, since this is the way the awareness arises?” (*NMI* 171.12)

The correspondence theory of truth is clearly presupposed by the Nyāya criterion of truth called efficiency of activity (*pravṛttisāmarthya*). The Naiyāyikas argued in favor of a pragmatic principle of confirmation. When one has an awareness of water, one goes toward the perceived water, and if this endeavor is efficient, that is, if one obtains water, then the awareness is true. Otherwise it is false (*NBh*, Introduction). The discussions of the efficiency of activity seem to presuppose a difference in the reliability of the senses. The awareness that has to be confirmed is usually a visual one, and the confirming awareness is of touch or taste (as in the case of water). The expression “efficiency of activity” is often interchangeable with the expression “obtainment of an object/purpose” (*arthaprāpti*). The Naiyāyikas argue that when the awareness is true the object is obtained, and when it is false the object is not obtained.

Another similar but different criterion of truth is used by Dharmakīrti and his followers. Dharmakīrti argues that the production of efficient action (*arthakriyākāritva*) indicates whether an awareness is valid or not. The difference between this and the Nyāya criterion is that the former is not used to prove that the object of the awareness is real. According to Dharmakīrti a false awareness can nevertheless be valid. Although all awarenesses that involve conceptual constructions are false, some such awarenesses (notably inferential awarenesses that always involve universals) lead to successful activity. Dharmakīrti likens their case to someone who mistakes diamond rays for the diamond itself (*PV*, 3.57). Although such a person acts on a false awareness, he or she is nevertheless successful in obtaining the diamond. Another

important aspect that distinguishes the Buddhist criterion from that of the Nyāya is that the object seen and the object obtained can never be the same. According to the Buddhists everything is momentary. Thus, the water seen and the water obtained are not the same water. Another difference between the two criteria is due to the rejection of the substance. The Buddhists denied that there is a certain substance such as water that has properties such as color and flavor. Thus, the seen water and the tasted water are in fact entirely different kinds of atoms that are only loosely connected by a causal relationship (PVSV 70.14f)

The preceding discussion treats the realistic schools. The topic of the criterion of truth in idealistic and illusionistic schools, which consider all empirical awarenesses to be false, arises from a different set of problems and specific metaphysical doctrines. For instance, certain Buddhist Yogācāras consider only those awarenesses to be true that have a correspondence in an unconscious awareness called *ālayavijñāna*. Vedāntins like Śankara (700?–750?) consider empirical awarenesses to be provisionally true until one attains the realization of the identity between ātman and brahman. Everyday awarenesses are like a dream. As long as the dream lasts, the awarenesses of the dream are considered true; when one wakes up they are realized to have been false. These positions, however, are usually ignored in the philosophical debates in classical India.

### A SKEPTICAL RESPONSE TO THE CRITERION OF TRUTH

Jayarāśi Bhaṭṭa (fl. c. 800), a skeptic philosopher loosely affiliated to the materialist Lokāyata school, raised a devastating critique of the various criteria of truth. The production by undisturbed causes, he says, cannot be used as a criterion, because it cannot be known whether the causes are undisturbed. The senses do not apprehend themselves, and therefore, cannot apprehend whether their functioning is disturbed or not. Nor can their proper functioning be inferred, because there is no inferential sign on which the inference can rest. If the correct awareness itself is considered to be such a sign, then the argument results in mutual dependence. The awareness is correct because the causes are undisturbed, and the causes are undisturbed because the awareness is correct.

Also, the absence of sublation cannot be used as a criterion of truth. At most one can say that those awarenesses that are sublated are false, but not that those that are not sublated are true. It is possible that sublations do not arise because some causal factor is missing. A person may have an illusion of water in respect to sun rays and not go toward the place of the sun rays. Thus, the causal

factor that could produce the sublation (the proximity) is absent and the sublation does not arise. Besides, one may simply die before the sublation is produced. It is impossible to know at any given moment which awarenesses are true and which are going to be sublated in the future. Jayarāśi's argument bears an obvious similarity to Karl Popper's assertion that the scientific doctrines one holds to be true are only those that are not yet refuted, but they are liable to be so in the future. Of course, the basic concerns of Jayarāśi and Popper are entirely different.

The efficiency of activity based on an awareness also cannot be used as a criterion of an awareness' truth because the claim of efficiency also has to be confirmed: it has to be apprehended and its apprehension has to be ascertained as nonerroneous by another efficiency of activity. It is not true that an awareness will give satisfaction if and only if it is true. To repeat James's example, the pragmatist claims that if one believes that there are tigers in India, and one goes to India and finds tigers there, then, to use the Nyāya terms, the activity is efficient and the awareness is true. However, as critics of pragmatism point out, one may go to Syria, find some tigers there and think that one is in India, or one may go to India and mistake some big cats for tigers, or one can even go to India find tigers and mistake them for cats. Thus, a confirming awareness must be confirmed in its turn, and this would lead to an infinite regress. The arguments against Nyāya apply to the Buddhist criterion of production of efficient action, except that the Buddhist faces some additional difficulties due to the doctrine of momentariness and the rejection of universals.

### VERBAL COMMUNICATION

The two main questions with which Indian philosophers who deal with verbal communication are concerned are: (1) What is the process by which one understands the meaning of words? (2) How does one know that words, once understood, are truthful? Concerning the first question see the entry "Philosophy of Language in India." This entry will focus only on the second question.

The veracity of words is crucial to Indian philosophers because knowledge derived from the sacred writings depends on it. Clearly, most religious doctrines could not be established by other means of knowledge such as perception or inference. Furthermore, when one is faced with a plurality of religious traditions, the question invariably arises as to which tradition can be trusted, for all of them cannot be true. Thus, each tradition had to adduce some arguments to justify the teachings it considered to be true. According to the Nyāya-Vaiśeṣika the

Veda was revealed to normal human beings by the Rishis who have direct knowledge of it, and consequently the truthfulness of the Veda, at least as known to one, depends on the truthfulness of the Rishis. Vātsyāyana (fifth century) enumerates three characteristics that must be present if one is to be considered a trustworthy or authoritative person: One has to have direct knowledge of things, compassion toward living beings, and the desire to teach things as they are.

There are basically two ways to prove the validity of a statement made by a reliable person. Either the reliability of the person making the statement is established, or the truthfulness of the statement is directly perceived or inferred. Ideally, the statement should be directly confirmed, but in the case of the Veda this is not always possible, for the truthfulness of a Vedic statement is often beyond the realm of examination by normal human beings, for example, statements concerning heaven. Vātsyāyana's proof is based on the assumption that the different parts of the Veda have the same authors. The statements of the Āyurveda and magical spells (*mantra*), which according to Vātsyāyana form a part of the Veda, have visible results. When certain spells that are intended to remove poison are uttered, the poison is actually removed. Furthermore, certain parts of the Veda proper also have visible results, for example, "One desirous of a village should perform a sacrifice" (*grāmakāmo yajeta*). Vātsyāyana's inference of the validity of the Veda runs as follows: From the parts of the Veda that have visible results one infers the trustworthiness of its authors (qualified by the three characteristics mentioned earlier), and because these are the same trustworthy authors as those of the rest of the Veda, the validity of the latter can be inferred.

The proof of reliability of a person was further developed by Dharmakīrti, who was concerned with the trustworthiness of the Buddha. It was clear to Dharmakīrti, who was conscious of the problem of induction, that the argument as it appears in *Nyāyabhāṣya* and *Nyāyavārttika* is not valid: Just because someone is trustworthy in matter x (e.g., medicine) does not necessarily mean he or she is trustworthy in matter y (e.g., rituals and sacrifices). Consequently, Dharmakīrti modifies the argument in two points. First, he does not simply draw an inference from trustworthiness in any part x to trustworthiness in any part y; he allows such an inference only when one moves from the main part of a teaching to its secondary part. Second, the logical reason used in Dharmakīrti's inference is not just the sameness of the author, but includes the motivations of the speaker in his reasoning,

for example, one should consider whether the speaker may have a motivation to lie.

More specifically the proof runs as follows: The main part of the Buddha's teaching are the four noble truths. These truths can be established independently of the Buddha's authority through perception and inference. Once the four noble truths are established, one can conclude that the Buddha was knowledgeable at least in matters of salvation. From such knowledge one infers that the Buddha has practiced various means for salvation for a long time (i.e., during many lives). However, he need not have practiced for such a long time had he been interested only in his own salvation. Therefore, his efforts were for the sake of other people. His engagement for the benefit of other (in fact, all) living beings in this manner presupposes compassion. Furthermore, the Buddha does not lie, because he has nothing to gain by lying. Therefore, the Buddha is trustworthy. Consequently, one can infer the truth in secondary matters in his teachings that are not open to an examination by normal human beings. As an example for such a domain Dharmakīrti mentions the law of karma. Later Tibetan commentators also mention certain monastic rules that cannot be established independently of the Buddha's word (Tillemans 1993).

Interestingly, the reliability of the Gods must also be established. The Śaiva commentator Sadyajyotis (ninth century) says: Why is the word of Śiva authoritative? Because he is a pure, infallible, gracious lord endowed with knowledge that extends to everything. And his words whose objects are seen can be perceived as fruitful. Therefore, it can be inferred that his words whose objects are not seen are fruitful in exactly the same manner (Franco 1997, pp. 41–42).

## THE OTHER PRAMĀṆAS

It is unfortunate that the other means of knowledge receive little attention in the Indian tradition. The Naiyāyikas and the Mīmāṃsakas have accepted analogy or comparison (*upamāna*) as a separate means of knowledge, but discussions about it remain rudimentary. It is defined as "proof of what has to be proved from similarity to something well known" (NS 1.1.6). The stock example for the use of analogy is: Someone does not know what a gayal is and is told "a gayal is like a cow." He or she then goes to the forest and is able to recognize a gayal on seeing it. Another example concerns the recognition of something from its name. For instance, knowing that the herb called bean leaf is like a bean, a person who finds this herb realizes that this is the thing to which the name applies. The Naiyāyikas were not unanimous as to what exactly constitutes the means of

knowledge in this case. The older Naiyāyikas argued that the statement of the instructing person is the means of knowledge; the later Naiyāyikas maintained that it is the cognition of similarity that brings about the understanding. Means of knowledge, by definition, must lead to an awareness of an object previously unknown, for if the object is already known, its awareness will be nothing but recollection, and, except for the Jainas, no school of thought accepted memory as a means of knowledge.

There was some uncertainty as to what exactly is new about the object of the awareness resulting from comparison. To repeat the stock example, when one recognizes that a certain animal is a gayal, it is not the animal as such that is the object of the comparison, because it is apprehended by sense perception. It is also not that there is a similarity between the cow and the gayal, because the similarity was already conveyed by verbal communication. Nor can the resulting awareness consist in the conclusion that the particular animal observed for the first time is a gayal, because in this case comparison would not be different from inference. Indeed, some Mīmāṃsakas who professed this opinion were criticized by the Naiyāyikas for reducing comparison to inference (Bhatt 1962, pp. 290ff). The Naiyāyikas (*NBh* 1.1.6) as well as some Buddhists of the Kushana period (Franco 2001, pp. 11–12) maintained that the result of comparison is the awareness of the designation, that is, that the animal seen in the forest is called gayal. Nevertheless, it remained controversial what distinguishes analogy from inference on the one hand and from verbal testimony on the other, and different opinions were put forward on this issue. The Buddhists, the Vaiśeṣikas, and the Sāṃkhya did not consider analogy to be a separate means of knowledge (Bhatt 1962, pp. 289–307).

Another potentially interesting means of knowledge that remained underdeveloped is *arthāpatti*. There is no agreed translation for this means of knowledge, and it is rendered by presumption, supposition, implication, negative implication, circumstantial evidence, and so on. The two most common examples for *arthāpatti* are: (1) Knowing that someone is alive and not finding him or her at home, one concludes that he or she is outside. (2) One is told that fat Devadatta does not eat during the day, and one concludes that he eats at night. The two examples are distinguished as presumption based on something seen (*dr̥ṣṭārthāpatti*) and presumption based on something heard (*śrutārthāpatti*). In later texts one distinguishes six types of presumption according to the six means of knowledge on which a presumption can be based.

The examples mentioned in this connection seem construed and artificial and are not taken from an actual philosophical discourse or from everyday life. For instance, presumption based on inference is illustrated as follows: One knows by inference that the sun moves (its movement cannot be perceived, but is inferred because it changes its place in the sky). However, things that move usually possess limbs such as legs. Thus, a conflict between two means of knowledge arises, and this conflict is resolved by the presumption that the sun has a moving power. Conflict or apparent contradiction (*anupapatti*) between two means of knowledge is the essential ingredient of *arthāpatti*, and the resulting presumption resolves the conflict. The contradiction must be apparent. If the contradiction is real, for example, two awarenesses about the same object, one perceiving it as silver and the other as mother-of-pearl, the way of resolving it is by rejecting one of the alternatives as false, not by making a new supposition. Among the important philosophical schools, only the Mīmāṃsā and Vedānta accepted presumption as an independent means of knowledge (Bhatt 1962, pp. 313–340).

The Bhāṭṭa Mīmāṃsakas accepted absence (*abhāva*) as a sixth means of knowledge. A discussion as to how mere absence or nonexistence can be an object of valid cognition appears already in *NS* 2.2.7–12. An objector argues that a negating cognition cannot be valid because it cannot refer to an object in reality. The objection is rebuked by reference to common experience. When some pieces of cloth are marked and some are unmarked, one can be told “Fetch the unmarked pieces,” and one is able to do so. The Naiyāyikas, however, just like the Vaiśeṣikas, the Sāṃkhya, the Buddhists, and the Prābhākara Mīmāṃsakas, considered absence or nonperception to be included in inference. Praśastapāda identified absence with inference from absence of effect to absence of cause.

## CIRCULARITY OF PRAMĀṆAS

A general objection to the *pramāṇas* as such has been raised from the earliest times. If everything is established by means of knowledge, how are the means of knowledge themselves established? If they are established by other means of knowledge, these other means also have to be established by yet other means of knowledge and thus an infinite regress results. If the means of knowledge were to establish one another, a circularity would result. If one claims that the means of knowledge need not be established, the initial position that everything has to be established by means of knowledge has been abandoned. Some claimed that the means of knowledge establish both their objects and themselves, just as a lamp illuminates itself

and its surroundings. However, it remained unclear how this metaphor should actually apply to the *pramāṇas*, and some, like Nāgārjuna (VV, verses 30ff) even argued that actually a lamp cannot illuminate itself.

## KNUTZEN, MARTIN (1713–1751)

Martin Knutzen, the German Wolffian philosopher, studied at the University of Königsberg and became an extraordinary professor there in 1734. Because he was a Wolffian, even though an unorthodox one, he never attained a full professorship in that Pietist-dominated school. However, because he was also a Pietist, Knutzen could never attain such a position in other German universities where Wolffians held the power of appointment.

Knutzen disagreed with Christian Wolff on several significant points. His *Commentatio Philosophica de commercio Mentis et Corporis* (Philosophical Commentary on the Relation between Mind and Body; Königsberg, 1735) was an attempt to reconcile Wolff's theory of preestablished harmony with the Pietist doctrine of physical influence. He extended the problem beyond Wolff, from the relation of soul and body to the interrelations of simple substances in general. In this and in a panpsychistic metaphysics, he was closer to Gottfried Wilhelm Leibniz than to Wolff. Knutzen, in his cosmological work *Vernünftige Gedanken von den Cometen* (Rational thought concerning comets; Königsberg, 1744), was one of the first philosophers in Germany to accept, at least partially, the Newtonian theory of gravitational attraction. His theological work was derivative and of little significance.

Knutzen's reputation is due more to his having been the teacher of Immanuel Kant than to his own significance. His influence on Kant has been much overrated. Recent research has shown that his influence was confined to the solution given by Kant in his first essay, *Gedanken von den wahren Schätzung der lebendigen Kräfte* (Thoughts on the true estimation of living forces; Königsberg, 1747), to the problem of the interrelation of substances, and to Kant's acceptance of Newtonian attraction. On the second point, Kant was also strongly influenced by the Berlin circle around Pierre-Louis Moreau de Maupertuis, even though Maupertuis himself was reluctant to accept attraction; and in accepting attraction as a real force and in trying to give a metaphysical explanation for it, Kant went beyond the Berlin circle, Knutzen, and Isaac Newton himself in his published statements.

Both Kant's "Wolffianism" and his "Pietism" have been attributed by some historians to Knutzen's influence; but although Kant received a Pietist education, he was never either a Pietist or a Wolffian. Kant always opposed Wolff's doctrines, and any Pietist influence came through the general philosophical influence of C. A. Crusius. Even an alleged influence of Knutzen's theology on Kant's religious philosophy has been disproven.

## KOFFKA, KURT

(1886–1941)

Kurt Koffka, one of the three founders of the Gestalt movement in psychology, was born in Berlin. In 1903 he went to the university there to study philosophy, and he is said to have had a special interest in Immanuel Kant and Friedrich Nietzsche at that time. In 1904 he moved to Edinburgh, and in the next few years his interest in psychology became increasingly strong. Soon after receiving his doctorate at Berlin in 1908, he moved to Würzburg, where he served as an assistant to Oswald Külpe and Karl Marbe. In 1910–1911 he taught at the Academy at Frankfurt am Main, and it was during this period, as a result of the joint deliberations of Max Wertheimer, Wolfgang Köhler, and himself, that the central notions of Gestalt theory began to emerge. In 1911 Koffka became a lecturer at the University of Giessen, and from 1919 to about 1927 he was assistant professor.

The early 1920s saw the founding of *Psychologische Forschung*, a periodical in which several of the original articles on Gestalt theory were originally published, and of which Koffka was for many years the editor. During this decade he traveled extensively: A visit to Oxford for the International Congress of Psychology in 1923 resulted in much wider recognition of Gestalt theory than had hitherto been possible, and in succeeding years he was visiting professor at Cornell, Chicago, and Wisconsin. In 1927 he took up permanent residence in the United States, having accepted a professorship at Smith College, Northampton, Massachusetts. In 1932, at the invitation of the USSR State Institute, he joined an expedition to Uzbekistan to carry out ethno-psychological research, but at an early stage he was forced to return because of illness. He remained intellectually active until his death. He is said to have been a person of considerable kindness and charm, with wide interests that included music, art, and travel. His friendship with Wertheimer and Köhler was lifelong.

To separate Koffka's distinctive contributions from those of Wertheimer and Köhler is not easy, since each was influenced considerably by the other two. Koffka's *The Growth of the Mind* was an attempt to apply Gestalt principles to child psychology, while *Principles of Gestalt Psy-*

*chology* was a comprehensive account of a wide range of psychological work up to 1935, with detailed theoretical discussion. One of his central claims was that it is possible to take seriously the advances of science while still finding a place for the concepts of meaning and value; indeed, scientific inquiries themselves suffer if one does not do so. An aggressive materialism or behaviorism was quite foreign to him, but the alternative to this for Koffka was a new approach, using the concept of Gestalt, rather than a return to vitalism or Cartesian dualism. In an interesting passage in *Principles of Gestalt Psychology* he called attention to the difference in intellectual climate between Germany and America. The more abstract and speculative ideas, in which many German scholars were interested, had to be kept in the background when Gestalt theory was presented to the Americans, whose “high regard for science, accurate and earthbound” was accompanied by “an aversion, sometimes bordering on contempt, for metaphysics that tries to escape from the welter of mere facts into a loftier realm of ideas and ideals” (p. 18).

Philosophically interesting contributions found in *Principles of Gestalt Psychology* include the distinction between the geographical and behavioral environments, a discussion of the criteria by means of which “things” in the behavioral environment are distinguished from “not-things,” and an attempt to reinstate the concept of ego. The behavioral environment is, in effect, the perceived world, the world of commonsense experience, whereas the geographical environment is the world as studied by the physical scientist. There are features in the geographical environment (such as infrared rays) that in ordinary circumstances are not present in the behavioral environment, whereas there are features in the behavioral environment (for example, the fact that two lines are grouped together when someone looks at them) that have no direct counterpart in the geographical environment. Examples of “things” are sticks, stones, clouds, and some types of fog; marginal cases are waves, words, and noises, while “a fog that makes our ocean liner reduce speed and sound its piercing horn is not thing-like at all, as little as the mist from which we emerge when we climb a mountain” (ibid., p. 70). The three characteristics of things are “shaped boundedness, dynamic properties, and constancy.” As for the ego, “it has a very definite place in that [the behavioral] world, and well-defined, if variable boundaries.... ‘In front,’ ‘to the left and right,’ ‘behind,’ and ‘above and below’ are characteristics of space which it possesses with regard to an object which serves as the origin of the system of spatial co-ordinates” (ibid., p. 322).

In this case science itself is seriously impoverished if the concept of the ego is simply ignored. The study (sometimes called phenomenology) of how the world appears at the commonsense level is logically independent, according to Koffka’s view, of any new discovery in physics about what is “really” happening.

Many of the problems that Koffka raised are of current philosophical interest, and as a psychologist he ranks among the greatest of his generation.

## KÖHLER, WOLFGANG

(1887–1967)

Wolfgang Köhler, the German Gestalt psychologist, was born in Tallinn, Estonia. He studied first at the University of Tübingen and then at Bonn. He next studied physics under Max Planck and psychology under Carl Stumpf at the University of Berlin, and received his PhD from that school in 1909 for investigations on hearing. In 1911 he became Privatdozent at Frankfurt. Max Wertheimer came to Frankfurt in 1912, and in the same year Köhler and Kurt Koffka served as the subjects for Wertheimer's famous experiments on stroboscopic motion that are widely regarded as the beginning of Gestalt psychology.

In 1913 Köhler became director of the anthropoid experiment station operated by the Prussian Academy of Sciences at Tenerife in the Canary Islands, and he remained there, throughout World War I, until 1920. The pioneering studies in the psychology of chimpanzees that he carried out there were published in several papers and in the monograph *Intelligenzprüfungen an Anthropoiden* (*The Mentality of Apes*, 1917).

Köhler's next major work, *Die physischen Gestalten in Ruhe und im stationären Zustand* (Physical Gestalten in rest and in the stationary state), was published at Brunswick in 1920. It is primarily a work in physics and reveals Köhler's indebtedness to Planck, but its major themes played important roles in his more strictly psychological writings.

In 1921, with Wertheimer, Koffka, Kurt Goldstein, and Hans Gruhle, Köhler founded the journal *Psychologische Forschung*, which served as the leading organ of the Gestalt psychologists until Köhler was forced to suspend publication because of the difficulties of editing it from the United States. In 1922 Köhler succeeded Stumpf as director of the Psychological Institute and professor of philosophy at the University of Berlin. He held a visiting professorship at Clark University in the academic year 1925–1926 and returned to America for another visit in 1929. In the same year his *Gestalt Psychology* was published in English.

Köhler was the only leading member of the Gestalt school who was not Jewish, but he was strongly opposed to the Nazis. He published a letter against them in a Berlin newspaper after they took power and a bit later left Germany. Köhler gave the William James Lectures at Harvard in 1934 and published them as *The Place of Value in a World of Fact* in 1938. In 1935 he was appointed professor of psychology at Swarthmore College. His Page-Barbour Lectures given at the University of Virginia in 1938 were

published in an expanded version in 1940 as *Dynamics in Psychology*. Köhler became professor emeritus at Swarthmore in 1957. In 1959 the school awarded him an honorary doctorate and he became visiting research professor at Dartmouth, a position he retained until his death.

Köhler is correctly thought of primarily as a psychologist. Nevertheless, throughout his career he never hesitated to interpret the results and methodology of the physical sciences and to apply his interpretations to the delineation of the proper task of psychology and to the elucidation of its problems. He admitted a debt to the phenomenology of Edmund Husserl, and his own work was broadly in the phenomenological stream. Both phenomenology and physics influenced his vocabulary, his methods of research, and his theoretical conclusions. Köhler was an ardent controversialist, and he engaged in a continuing polemical defense of the Gestalt theory. He believed that the theory offered a new resolution of the controversy between those who believe in innate ideas or tendencies and those who stress the importance of ideas acquired by learning. He thought that his Gestalt physics could resolve the biological controversy between mechanism and vitalism. He claimed to have dissolved the philosophical controversies between idealism and realism and between monism and dualism, and he advocated a form of epiphenomenalism or even an identity theory of mind and body. Köhler believed that by phenomenological analysis he could demonstrate both the existence and something of the nature of value, and that value, or "requiredness," was more general than moral philosophers and aestheticians believed; thus, he held, the psychologist's investigation of value was of prime importance to the philosopher.

Köhler, then, not only advanced psychological theories and views about the proper subject matter of this science but also presented well-reasoned opinions on speculative problems in biology, physiology, physics, and chemistry, and suggested possibly fruitful lines of research for these sciences to undertake. He also presented theories belonging to such central philosophical disciplines as epistemology, metaphysics, and value theory. This entry will discuss some of the philosophically interesting issues raised by Köhler in the physical sciences and psychology, as well as some of his general philosophical positions. It will not attempt to discuss his contributions to Gestalt psychology proper, except for his discussion of isomorphism.

## PHYSICS AND PHYSIOLOGY

Köhler discussed physical concepts and discoveries for at least three main purposes: to demonstrate the existence of physical structures analogous to perceptual gestalten; to provide a physicochemical theory of perception and other mental functions; and to delineate the proper task of psychology by comparing its present status with the status of physics at various times in its history.

**PHYSICAL GESTALTEN.** Köhler, like the other Gestalt psychologists, claimed that a central subject of psychology is the investigation of certain kinds of structures in which “the whole is more than the sum of its parts.” An analysis of these gestalten would explain many puzzling facts of vision, touch, hearing, memory, and understanding. The existence of such structures was denied on the ground that the whole can never be more than the sum of its parts. Köhler sought to show that there are a variety of recognized physical systems in which the whole is more than the sum of its parts. Machines are structures whose movements are strictly determined. From a knowledge of the parts of a machine and their interrelationships, we can know the motions of the whole. Thus a machine, according to Köhler, is no more than the sum of its parts. But in many physical systems it is the state of the whole that determines the state of the parts. Examples of such systems are the distribution of an electrical charge over the surface of a conductor, which varies with the shape of the conductor; the distribution of a current of electricity or fluid in a network of wires or pipes; the distribution of particles of a fluid body whose only constraint is the walls of the container; and a planetary system. The common characteristic of these systems is that the parts interact dynamically rather than mechanically. And in these systems, he claimed, the whole is greater than the parts.

These physical systems all exhibit another characteristic, which Köhler thinks is strikingly analogous to a characteristic of phenomenal gestalten. When the physical systems are disturbed, the interaction of their parts tends more or less rapidly to restore the systems to a state of equilibrium. They are thus dynamically self-regulating systems. Phenomenal gestalten are also dynamically self-regulating. The parts of the gestalten interact with one another to produce, or reproduce, systematic wholes within the perceptual field. Köhler recognizes, following Wertheimer, a set of five factors involved in the recognition of gestalten. If any of these factors are present, then we tend to perceive a gestalt, unless inhibiting factors are also present or the factors are so present as to cancel out one another. The five factors are (1) *proximity*: Objects

that appear close together are more likely to be classed as part of the same gestalt than those which are far apart; (2) *similarity*: Objects that resemble each other tend to be classed as belonging together; (3) “*common destiny*”: If objects move or change together, they tend to be perceived as part of the same thing or as belonging together; (4) “*good gestalt*”: Forms that are not quite regular tend to be perceived as more regular than they are; (5) *closure*: Forms that are in some way incomplete tend to be perceived as complete—for example, a circle with a small arc missing will be perceived as a full circle.

The resemblance between dynamically self-regulating physical systems and phenomenal gestalten suggested to Köhler that it might be more fruitful to attempt to understand mental phenomena by means of a dynamic rather than a mechanical model, and in fact this model continued to serve Köhler throughout his career as a fruitful explanatory hypothesis in psychology. He was particularly successful in applying it to problems of perception, of memory, and of intelligence or insight—of coming to understand a situation or a problem.

Despite Köhler’s apparent success in applying the two notions that in certain physical and phenomenal structures the whole is greater than the sum of its parts and that psychological phenomena should be interpreted dynamically rather than mechanically, they have been widely criticized. Both notions, it is said, are enormously vague. It is not surprising that they seem to “work,” for by their very vagueness they can be made to fit almost any body of facts. Surely in some generally accepted sense of “whole” and “part” almost any whole can be shown to be greater than the sum of its parts. But it is not clear that Köhler was applying the two terms univocally in the phenomenal cases he adduced as examples, and it is even less clear that he was using them in the same sense when speaking of the parts of phenomenal gestalten and of the parts of physical systems. Similarly, although the dynamic model may have aided Köhler in the design of new experiments and the interpretation of many phenomenal facts, it has been claimed that, outside of a certain limited range of cases, the apparent use of a dynamic model can mean no more than a recognition that phenomena change. The substance of the theory is probably Wertheimer’s set of dynamic factors, which had in large part been anticipated by earlier psychologists, and there seems no reason to connect them with any specific physical theory.

**ISOMORPHISM.** Probably the most central concept in all of Köhler’s thought is isomorphism, or similarity of form. He used this notion for two major and several

minor purposes. The two major functions combine into a theory of knowledge that is partly conceptual and partly physicochemical and physiological. Köhler distinguished between (1) phenomena, or percepts; (2) their cortical correlates, or brain-states; and (3) nature, or the physical world. He was perfectly willing to believe that percepts and brain-states may eventually be shown to be identical and in this sense does not exclude the possibility of a metaphysical monism. He holds, in opposition to both phenomenologists and new realists, that the phenomenal world and the physical world are not identical, and thus is an epistemological dualist. (These points are discussed below.) It is the theory of isomorphism that serves as the connecting link among these three elements. Percepts, it is claimed, are related to one another within the phenomenal field as their cortical correlates are related to one another in the cortex and as the corresponding physical objects are related to one another in physical space. The structural relations within any of the three realms are reproduced in the others. If a man-percept appears in phenomenal space atop a horse-percept, then in physical space there is a man atop a horse, and in the brain there are two brain processes dynamically related to each other in the cortical correlative of the relation “on top of.”

What concerns us here is the isomorphy between the phenomenal world and brain-states. In this connection Köhler formulated the principle of isomorphism for spatial relations (it can be formulated for any type of phenomenal ordering) as: “*Experienced order in space is always structurally identical with a functional order in the distribution of underlying brain processes*” (*Gestalt Psychology*, Mentor edition, New York, 1959, p. 39). The parts of the visual field are not independent of one another; they exhibit structural relationships. If, for example, there is in my visual field a white square on a black ground, then in my brain there are processes corresponding to the white square, the black ground, and the boundary between the two. The topological relations between the brain processes are functionally identical with the corresponding visual relations. Metrical relationships are not preserved, but such relationships as betweenness are. In memory, these relationships are preserved in memory-traces. Thus it is form or structure rather than exact pictorial images that are preserved.

Köhler holds that the physiological processes in the brain that are involved in perception and memory are very probably electrochemical in nature. In the case of the white square, the brain process corresponding to the square-percept contains a higher concentration of ions than the brain process corresponding to the black

ground. The two processes are functionally connected at a boundary corresponding to the edge of the square. There is a potential difference across this boundary; an electric flow of ions therefore takes place, and the square is perceived. Changes in the solution leave memory traces, which are subject to alteration in the course of time. These traces are superimposed on one another and thus functionally mirror the order of time of the percepts themselves.

The theory of isomorphism, both in its conceptual outline and in its physiological accompaniment, has been only inadequately outlined here. The physiological element, despite the important role it plays in Köhler’s claim that functionally an identity theory of mind and body is at least feasible, is a matter for empirical investigation. Much of what Köhler says sounds rather plausible, but there are difficulties in stating the theory with the proper degree of precision. Although he speaks of a cortical retina, Köhler does not mean that perception involves the reproduction of a (two-dimensional or three-dimensional) image of the object within the cortex. This would be complete isomorphism. On the other hand, almost any set of relationships can represent any other by some form of correspondence, and the correspondences, if any, actually involved in perception might be very complex or in some other way not what we would intuitively grasp as a correspondence.

There are other issues involved that can only be raised and not explored here. Suppose it were established that when a certain macroscopic brain-state is observed in people, they generally claim to perceive a certain object. For instance, take any of the reversible figures that appear to an observer now in one way and now in another, such as a Maltese cross, composed of alternating black and white rays, which can be seen in two different ways. In one way of looking at it certain parts appear as the figure and the others as ground, while in the other way what was ground appears as figure and what was figure appears as ground. According to Köhler, each way of seeing the figure corresponds to a different electrochemical state in the brain. Now suppose that one person’s descriptions of the cross fail to correspond, in either a regular or irregular manner, to the descriptions that we have generally found associated with his brain-states. We may wish to claim that he is misdescribing what he is seeing. But how we choose to regard the situation is not merely a matter of fact; it involves at least one conceptual matter, a choice between conflicting criteria of what the person is seeing—the person’s description (which is, of course, the only criterion we now have) and our knowl-

edge of his brain-states. And empirical investigation alone cannot settle this conflict.

The same point applies to another example, in which a further factor becomes apparent. There is experimental evidence that when people see two parallel lines close to each other, one of which extends beyond the other at each end, they claim to see shadowy lines connecting the ends of the two lines to complete a trapezoid. Köhler suggests that the shadowy lines are caused by potential barriers in the cortex created by the cortical correlates of the lines actually drawn. Again, if it could be shown that such potential barriers are present in a person's brain although he claims not to see such lines, we might put it down to misdescription. But surely here we are inclined to take him at his word. In the first case we can describe what it means to see the cross in one way rather than another. But in this case we can only point out where the shadowy lines ought to be seen. The achieving aspect of perception is perhaps more obvious here. It is not simply a matter of what is seen but also of how we learn to describe what we see. In most descriptions it is clear what the standards of an accurate description are, and we can understand a proposal for a change in standards. In the present case it is not even clear what the standards are, if there are any. It is this element of conventional standards, which Köhler has omitted from his discussion, that makes his problems of the relationship among percepts, objects, and brain-states not merely a matter of physiological and psychological experimentation but of conceptual analysis.

*Isomorphism and language.* Köhler developed an interesting linguistic theory as a corollary of his theory of isomorphism. This corollary, except for Köhler's added complexity, resembles the picture theory of meaning advanced by Ludwig Wittgenstein in his *Tractatus Logico-Philosophicus* and seems to have been developed out of similar considerations. If the only way one thing can represent another is by having the same form, then the only way language can represent a situation is through a common form. Since, according to the theory of isomorphism, a phenomenal event has a physiological correlate possessing a similar form, then language represents both the event and the physiological correlate indifferently. A statement ostensibly about an observed phenomenon can be interpreted as a statement about brain-states and vice versa: ". . . language . . . is the peripheral outcome of antecedent physiological processes, among others of those upon which my experience depends. According to our general hypothesis, the concrete order of this experience pictures the dynamic order of such processes. Thus, if to me my words represent a description of my experi-

ences, they are at the same time objective representations of the processes that underlie these experiences. Consequently, it does not matter very much whether my words are taken as messages about experience or about these physiological facts. For, so far as the order of events is concerned, the message is the same in both cases" (*Gestalt Psychology*, p. 40).

**PHYSICS AND PSYCHOLOGY.** The third way in which Köhler has used physics is to elucidate what he regards as the proper program for psychology. Physics, in his view, is an old, established discipline whose techniques have been developed and refined over a long period of time. Quantitative methods and pointer readings are appropriate in physics because there are thoroughgoing and widely accepted theories that give meaning to the numbers arrived at. Even in the early days of physics, in the time of Galileo Galilei, many of the problems could be investigated quantitatively, because the phenomena investigated had long been known from everyday life and this knowledge provided the necessary qualitative meaning. Where everyday life did not supply the necessary qualitative background, as in the study of electricity, physics had to proceed by qualitative investigations before quantitative ones could be undertaken profitably. The problems of psychology, Köhler claims, are more often like those of electricity than those of Galilean mechanics. In general, in psychology the necessary meaning-giving theory is absent. Intelligence quotients are notoriously hard to interpret. The difficulty in assessing their significance arises out of a lack of any clear notion of what intelligence consists in. Psychology should first try to develop a theory of intelligence before it tries to measure intelligence. Until a satisfactory theory is arrived at, it can hardly be determined whether or not intelligence quotients do measure intelligence and how well they do it.

## GESTALT PSYCHOLOGY

**CRITIQUE OF BEHAVIORISM.** Köhler's attempt to show that qualitative methods are the most appropriate in the present state of psychology arose in the context of his repudiation of behaviorism. His phenomenological view of the nature of the subject matter of psychology was radically different from the notion that psychology is the study of behavior, with its related stimulus-response physiological theory. The behaviorists, according to Köhler, have taken too much to heart one epistemological teaching but ignored its wider context. They seek to limit psychology to the observation of the response of human beings in scientifically controlled situations because they

have become aware of the truth that one person cannot directly observe another person's experience. However, the behaviorist cannot avoid the study of direct experience by limiting himself to the observation of human reactions in controlled situations, for the only evidence he has of such reactions is his own experience. The behaviorist seeks to be objective, but he confuses two pairs of meanings of the terms *subjective* and *objective*. In one sense, observations of another person's reactions are no less subjective than my hearing his statements about what he is experiencing: Both are part of my experience. But in the primary sense *subjective* and *objective* refer to differently characterized phenomena within my experience. In this sense there is no reason why I cannot examine both subjective and objective experience; in the first sense I cannot help but investigate subjective phenomena.

**CRITIQUE OF INTROSPECTIONISM.** Whereas Köhler criticized behaviorism for misunderstanding the nature of direct experience, he criticized introspectionism for distorting the facts of experience to fit a preconceived theory. By "introspectionism" Köhler does not mean the gathering of information from an inspection of one's own experience in general; he has criticized the behaviorists for their refusal to accept information so gathered as unscientific. When he attacks introspectionism, Köhler has in mind certain characteristic theories and procedures of the psychologists of his own and the previous generation who relied on introspection. Philosophers and psychologists long believed, under the influence of geometrical optics, that, for example, a round penny must appear elliptical in most positions or that a white surface under a very low degree of illumination must appear gray, and a darker gray than a black surface under a very high degree of illumination. Experimentation has shown, however, that a "naive" observer tends to describe the penny as round no matter what shape strikes the retina and the white surface as white in almost any circumstances. The naive observer, it was held, could not be seeing what he claimed to be seeing. Introspectionists devised elaborate techniques by which a "trained" observer could be made to claim to see what by the laws of optics he should be seeing. In essence, these techniques consisted in excluding from the visual field of the observer all of the surroundings of the object to be observed. In this way, the introspectionists claimed, all the factors of learning are excluded and the object is seen as it "really" appears, before the process of education has distorted our pristine perceptions.

Köhler rightly points out that by employing this technique of exclusion in the interests of a theory, all

other factors that might explain why the round penny looks round have been barred. The Gestalt theory offers an alternative explanation of this fact that does not involve the notion of an elaborate hoax played upon the naive observer, an explanation that cannot even be tested by the exclusionary techniques of introspectionism. The defects of introspectionism were further evidenced, Köhler claims, by the fact that introspective psychology had degenerated into an investigation of minute and trivial facts of interest only to specialists.

**ASSOCIATIONISM AND ATOMISM.** Köhler criticized both the introspectionists and the behaviorists for their psychological atomism or, as he also called it, their mosaic theory. Closely related to psychological atomism is the theory of associationism, which Köhler likewise regarded as inadequate. Psychological atomism is the view that what we perceive is a mosaic of bits and pieces, each independent and essentially unconnected with any other. The parts of the visual and other sensory fields thus lack any sort of relatedness. Yet we do recognize this brown patch and that white patch as belonging together and both as being parts of a dog, rather than one belonging with the ground underneath the dog and the other to the wall behind the dog.

Psychological atomism, according to Köhler, is a theory about the nature of the objects of perception. The theory of association is a theory as to how the experience of order arises out of the unordered psychological atoms postulated by psychological atomism. I have seen white patches associated with dogs in the past, and thus I come to expect that when I see a white patch of a particular kind in the future, it will belong to a dog.

Köhler's answer to psychological atomism is that we do not experience the parts of the visual field, for example, as separate from and unrelated to one another, but that we experience relationships among its parts. Certain wholes separate themselves from other parts of the field, and these wholes are composed of parts related to each other by means of the Wertheimer factors mentioned earlier. If we are in fact led to see things as belonging together by the very structure of experience, then the theory of association is unnecessary. Köhler went on to show that it is also inadequate, in that it cannot fully explain all that it was intended to explain.

Many of Köhler's criticisms of atomism and associationism as psychological theories are justified. But he apparently thought that in arguing against psychological atomism he was also arguing against any epistemological atomism as well. Part of his theory of isomorphism is the

claim that the world as experienced contains experienced relationships among its constituents and that the observer does not add this structure to the world. But here, as earlier, conceptual matters are involved: It is not only a matter of experienced relationships but also of learning what it is to experience a relationship. We must learn the established criteria of what is to count as a relationship before we can know that what we are experiencing is a relationship.

Köhler also believed that the theory of associationism led to a hidden limitation in methods of investigation. According to the associationist, he holds, organization arises out of previous association, whereas, in his view, association depends on previous organization. Sensory gestalten, melodies, and meaningful sentences are organized wholes, and their parts are readily associated. Totally unrelated visual or auditory objects or nonsense syllables, on the other hand, have first to be organized into some kind of order before they can be recognized or be later remembered as having been associated. Köhler does not deny the facts of association but, rather, that association is a fundamental explanatory category. If it were recognized that order is more easily found than made, then it would be seen that organization should play a role in the design of experiments. As it is, far too many experiments fail. For instance, in experiments designed to test an animal's intelligence the apparatus may be too complex for the animal to grasp the relations of the parts and thus be beyond his capacity, whereas by a slight revision the apparatus could serve adequately in carrying out the experiments.

## PHILOSOPHICAL PROBLEMS

**EPISTEMOLOGY.** Köhler's epistemological views are difficult to organize and apparently are not altogether consistent. Probably the most careful and accurate presentation of his views is found in *The Place of Value in a World of Fact*. His theory is, as he claims, a form of epistemological dualism, here couched in the form of a refutation of both phenomenalism and the new realism and aimed at showing that the body-mind problem is a pseudo problem. Köhler's theory, both in content and in terminology, is strikingly similar to that developed by Bertrand Russell in *The Analysis of Matter* and *The Outline of Philosophy*.

The body-mind problem, Köhler claims, concerns the location of percepts. Physiology tells us that they are in our interior, in our brains, yet they appear to be outside ourselves. The resolution is that percepts are inside our bodies in one sense and outside our bodies in quite a

different sense. We should distinguish between the body as a physical organism and the body as a percept. Percepts depend on processes within the physical organism; without such processes they would not take place. They appear as located outside the body, which is itself a percept. This perceptual body has a definite place in perceptual space, and other percepts have a definite relation to it within perceptual space. There is no more need to wonder why a perceptual dog appears outside of my perceptual body than to wonder why it appears outside of a perceptual house. Relationships in perceptual space say nothing about the location of percepts in physical space.

In some way what Köhler was saying has been recognized at least since Immanuel Kant's distinction between phenomena and noumena, and Köhler's position seems open to much the same objections as Kant's. What is needed is an account of the relationships between physical space and perceptual space, or between physical object and percept, and this is not what Köhler has given. In physical space percepts are inside the observer's body; in perceptual space they are outside. Here is a radical disparity between spatial relations in the phenomenal and the transphenomenal realms. But Köhler wants to hold that relationships in the phenomenal and the physical worlds are isomorphic. The phenomenal house is between two phenomenal trees; the physical house is likewise between two physical trees. Phenomenal relationships are thus supposed to give us knowledge of physical relationships. And our knowledge of phenomenal relations is the only basis for any knowledge we may have of physical relations. But how do we get from percepts in the physical world to physical objects? And how can we avoid solipsism? Köhler claims that two scientists do not observe the same galvanometer. It is self-evident for him that neither can observe the other's phenomenal world. But physically the percept of each is different, for each is in his own brain. Köhler has not shown how we get from the two percepts to a common physical object.

That Kant spoke of things-in-themselves and Köhler of a physical world, or of nature, should not mask the fundamental similarities of their views. Despite Köhler's belief that the phenomenal world itself gives evidence of a nonphenomenal world, his physical world stands in exactly the same position as Kant's things-in-themselves. They are both unknowable.

**CAUSATION.** With his emphasis on experienced relationships between the parts of perceived entities, it is not surprising that Köhler denies David Hume's claim that we do not experience causal relations. Causation is only a

special case of a general characteristic of experienced phenomena that Köhler terms *requiredness*, other cases of which are discussed in the section on value. In any of various ways one experience “demands” another for its completion. What Köhler calls insight is the coming to see what is demanded, what is needed to complete a set of factors. Men, and animals to a more limited degree, can have insight into, among other things, what caused a particular event or what will be the probable outcome of a particular line of action. The insight is the experiencing of a causal relation between cause and effect. Köhler concedes that the Humean theory of regular sequence accounts for our practice in various situations of subjecting causal theories to experimental testing after they have occurred to us, but it cannot by itself account for our first recognition of a cause.

Köhler has been criticized by defenders of the regularity theory for confusing psychological issues with logical ones. It may well be the case that in human (as well as in purely physical) situations we frequently arrive at the true answer to a causal problem without any elaborate examination of classes of sequences. From this, however, it does not follow that causation is a “simple” relation like, for example, coexistence that can be given in a single experience. Granting that I may truly judge that  $A_1$  is the cause of  $B_1$  without having performed elaborate controlled experiments, Hume’s regularity theory has nevertheless been vindicated as an analysis of the concept of causation if I am prepared to admit that  $A_1$  was not really the cause of  $B_1$  were I to discover that other instances of  $A$  are or were not followed by instances of  $B$ .

**VALUE.** Köhler’s epistemological views are developed most fully in *The Place of Value in a World of Fact*. This volume is a contribution to the discussion of axiology that played such a prominent role in American philosophy during the 1920s and 1930s. The argument of the work is long, digressive, and difficult to summarize. The views on isomorphism and on epistemology mentioned above form an integral part of the argument. At the cost of oversimplifying Köhler’s views to the point of distortion, it can be said that he holds that we can have direct perceptual knowledge of value. Value is an objective fact of the phenomenal, and hence also of the physical, world. Both phenomenal gestalten and physical gestalten spontaneously change in a certain direction. Melodies and visual shapes require completion in certain ways. Very often when we are attempting to remember something, the context in our mind shows us not only the sort of thing we seek to remember but also whether we are getting close to remembering it. Whatever the proper inter-

pretation of these phenomena may be, Köhler believes that they all demonstrate the factor that he terms *requiredness* and that in the case of memory, the requiredness is a characteristic of something outside the present phenomenal situation. Valuation, an assessment of what ought to be, is not a unique phenomenon but another special case of the recognition of requiredness. Köhler does not directly undertake an analysis of valuation but only of requiredness in general. He hoped that his analysis would be of use to philosophers in their own analyses of ethical and aesthetic requiredness.

**MECHANISM AND VITALISM.** Toward the end of *The Place of Value in a World of Fact*, Köhler returns to two topics that had engaged him earlier, the dispute between mechanism and vitalism and the question of the precise metaphysical classification of his own theory. In the first case, as in many other situations, Köhler argues that the apparent alternatives are not exhaustive. Mechanists, in their treatment of living processes, take the same short-sighted view that they take of the nature of physical processes mentioned earlier. Mechanical systems are not the only kind of physical systems; there are also the dynamically self-regulating systems. The premise that man must be a machine because physics finds only mechanical systems in the world is thus undermined. On the other hand, one does not have to hold to vitalism just because men are obviously different from machines. Living organisms, including man, can quite easily be physical systems without being machines. And in fact, Köhler held, living organisms can be explained quite satisfactorily as dynamically self-regulating systems without postulating some mysterious nonphysical vital force.

**BODY-MIND PROBLEM.** Köhler seems to advocate an epistemological dualism. He was not, however, a dualist in the sense in which the term is used in connection with the body-mind problem. Other psychologists have labeled him a physicalist, and he did not totally reject the terms *materialist* and *monist* as used to describe his metaphysical views. He found the label “materialist” misleading because he accepted the modern physicists’ account of the world, and this account is very different from any traditional account of matter as composed of solid impenetrable particles. He believed that eventually it may be shown that phenomenal colors are identical with chemical states in the brain and that in this way the physicists’ account of reality would be complete. In this sense he did not reject the possibility that monism is true, but in the meantime phenomenal qualities appear so different from any physical correlates that the possibility of the false-

hood of monism likewise cannot be ruled out. There is some similarity between Köhler's views on this subject and the theory of J. J. C. Smart and U. T. Place that sensations and brain processes are identical. Like Smart and Place, Köhler argues that the undeniable phenomenological differences between colors and chemical states of the brain do not rule out the possibility that, in an important sense, they may nevertheless be identical. However, unlike Smart and Place, Köhler does not claim that such an identity has in fact been established.

## KOREAN PHILOSOPHY

Scholars hold diverse opinions on the identity and origin of Korean philosophy. Although some trace the origin back to antiquity when the mythical figure Dangun supposedly founded the country in 2333 BCE, there is little historical evidence to support it. It is more plausible to estimate that philosophy began in Korea during the Three Kingdom era (second century CE) when people unfettered themselves from myths, legends, and shamanist beliefs of the tribes, and began to think in more general and philosophical terms. During this period Buddhism, a systematic and conceptually advanced religion, was introduced into the Three Kingdoms (Shilla, Baekje, and Koguryo), all of which embraced it to serve as a social and spiritual foundation for a trans-tribal ethical system. After its introduction, Korean Buddhism went through diverse phases of changes and developments, sometimes as a result of adaptations to changing social and political environments and sometimes as a result of theoretical debates. Neo-Confucianism and Western thought that were later introduced to Korea underwent similar turns and twists.

Korean philosophy, largely formed on the basis of external thought and influences, is notable not for the uniqueness of thoughts per se, but for the special manner in which it internalized the established and widely disseminated thought systems of Asia and the West and developed them into identifiably Korean forms. Korea's geographical and historical circumstances exposed the country to sudden and often torrential influxes of mature and powerful foreign culture and thought systems. Thus, the development of Korean philosophy has consisted in selecting an appropriate trend of thought carefully and reinterpreting it to meet the challenges of the society.

Because Korean philosophy had to concentrate on the selected trend, its characteristic is fundamentalist in that there was a tendency to select a specific trend or interpretation and adhere to it as the only source of truth to the exclusion of other trends. Because Korean philosophy attempted to synthesize diverse thought within the selected trend in order to meet the challenges of the soci-

ety, the ability to weave divergent thoughts into a coherent whole was crucial. Even today when Western philosophy prevails, the two characteristics of fundamentalism and integrationism are still valid as a description of Korean Philosophy.

### THE BEGINNING OF PHILOSOPHICAL THINKING—THE INTRODUCTION OF BUDDHISM AND THE DEVELOPMENT OF KOREAN BUDDHIST PHILOSOPHY

As the Three Kingdoms expanded to constitute sovereign states, politics began to separate from religion. Tribal federations were gradually transformed into monarchies, and the mythologies of clans and the associated religious rituals that had so far dominated the spiritual world of people were no longer adequate to serve as the basis of a state. This created a need for a unified belief system that would reconcile diverse native religious thought and practice, and provide a political rationale for the monarch-centered sovereign state. Such an ideology was also needed to counteract the aristocrats who resented the increasing concentration of political power in the monarch. The introduction of Buddhism from China at this time filled just this need, and it was welcomed by the royal authority.

From its inception Buddhism was allied with the royal authority, so it was advocated not only as a higher, more sophisticated religion, but also as a theoretical ground for strengthening the sovereignty. For example, the Buddhist notion of cause and effect, together with its karmic associations, were helpful in promoting the belief that their king was not a ruler arbitrarily chosen by Heaven, and that his status was a necessary consequence of the good deeds done in his past lives. Buddhist doctrines were also invoked to justify the authority and legitimacy of the royal rule. For that reason the Three Kingdoms endorsed at first the School of Precepts (the Vinaya School), which stressed the importance of rule abidance, in order to solidify the ethical norms and regulations of the newly established nations. As the number of Buddhist monks increased, their mission extended beyond the performance of ceremonies and rituals; they started to study the Buddhist doctrines and texts from a scholarly point of view.

Koguryo, in the north of the Korean peninsula, adopted a branch of Buddhism that interpreted Buddhism in terms of the Daoist concept of nothingness, a concept that was familiar in the local shamanist beliefs. It was succeeded by the Three Treatise School (the Madhyamika School), which upheld the doctrine of emptiness

(*Sunyata*) with the motto “What can be said, cannot be real.” Whereas Buddhism, with an emphasis on nothingness or emptiness, was popular in Koguryo, a different perspective on Buddhism was embraced in Shilla. It was called the Consciousness-Only School (the Yogacara School). As the name suggests, their main claim was that the external world is nothing more than the objectification of inner cognitive activities and that only consciousness and cognition exist. It was popularized by Shilla monk Woncheuk (613–696), who studied and practiced his theory in China. His theory was influential not only within Shilla, but also in Tibet.

After the seventh century, more monks returned after studying abroad and brought with them Buddhist doctrines of numerous schools, adding diversity to the early Korean Buddhism. It also improved the quality of Buddhist studies, but at the same time it caused deep confusion. All the teachings were from one Buddha. So how could one make sense of all these diverse interpretations, some of them in conflict with others? The perplexity was especially acute in Shilla, which had an alliance with Tang China and sent many monks there to study Buddhist doctrines. This created fierce debates and disputes among the monks, each group arguing that what it had learned was the exclusive truth. Through this process, conflicting theoretical stances adjusted themselves to accommodate each other, which led to the unique characteristic of Korean Buddhism called *integrationism*.

Shilla monk Wonhyo (617–686) was the first Buddhist scholar who established his own unique theory. He meticulously analyzed three core concepts of Buddhism—mind (*citra*), enlightenment (*bodhi*), and ignorance (*avidyā*)—and attempted to illuminate their mutual relationship. According to Wonhyo, Buddha’s mind and people’s minds are one and the same and people born with the mind of Buddha lost track of the true facet of human existence because they are blinded by ignorance (i.e., self-centeredness and greed). Thus, being in the state of Buddha’s mind (enlightenment) is nothing above and beyond being in the state of freedom from ignorance and thus returning to the original state of the human mind. On this basis, he argued that the Three Treatise School’s method that tried to reach Buddha’s mind by removing ignorance and the Consciousness-Only School’s converse method of removing ignorance by reaching Buddha’s mind were just two different paths to the same goal. This illustrates the way in which Wonhyo attempted to harmonize doctrinal differences among diverse schools. Because of Wonhyo’s influence, the Buddhist schools in Korea henceforth sought in a single-

minded way to reach an all-encompassing interpretation of Buddhism.

Whereas Wonhyo laid the philosophical foundation of Korean Buddhism, Uisang (625–702) focused his work on unifying numerous Buddhist schools active in all parts of the nation. Upon his return from Tang China shortly after Shilla absorbed and consolidated the other two kingdoms into the United Shilla (676), Uisang reorganized the Buddhist temples with divergent doctrinal allegiances by embracing the Flower Garland School (the Avatamsaka School). On the basis of the claim that particulars and universals, many and the one, were all different aspects of dharma (the principle, law, or a universal norm that orders both the natural world and human conduct), he advocated the holistic view that all things in the universe, causally interconnected under dharma, represented the same supreme mind. This holistic doctrine of the Flower Garland School provided a spiritual background for the harmony that must exist between individuals and the state, and between individuals and the universe. Thus it helped support the political consolidation of the Unified Shilla dynasty.

#### THE ACCEPTANCE OF ZEN BUDDHISM AND ITS DEVELOPMENT

In the eighth century the Unified Shilla made great strides in doctrinal studies, particularly in the areas of the Flower Garland and Consciousness-Only Schools. During the latter half of the eighth century, however, the role of king shrank to that of a protector of his own clan, and powerful clans in the provinces rose to supersede the royal authority. Accordingly, the Flower Garland School that provided the spiritual basis for unification was succeeded by Zen Buddhism backed by regional aristocrats. Zen Buddhism emphasized that enlightenment was attained not through laborious doctrinal studies, but through discovering the Buddha mind within oneself. Even though Korean Zen Buddhism prospered as diverse branches of Chinese Zen Buddhism were introduced, the philosophical message was no different from what had been taught by Flower Garland School or Wonhyo—that ignorance is the beginning of enlightenment and that everything is dependent on one’s mind. It should be noted, however, that practice-oriented characteristics of Zen Buddhism paved the way for Korean Buddhism to become a popular religion without being trapped in theoretical intricacies.

In 936 the Koryo dynasty emerged, leaving behind the chaotic ruins of the Shilla dynasty. While the Koryo dynasty was developing into a state, it exploited Confucianism for practical purposes. Confucianism was intro-

duced into Korea around the second century BCE and Koreans were familiar with its major teachings for more than 1,000 years. Although Confucian education was gradually strengthened mainly for the purpose of building a bureaucratic system, Koryo Confucianism at this time had yet to reach a level of philosophical significance. Spiritually, the primary concern of Koryo was integrating diversified schools of thought, and it was still Buddhism that undertook the role. Thus, one can witness the strong integrationist tendency in Buddhism throughout the Koryo dynasty.

Chinul (1158–1210) invigorated and established Zen Buddhism as a strong tradition in Koryo by providing it a firm philosophical basis. Thinking that Zen Buddhism of his time had dwindled in popularity mainly because of its inherent subjectivity and excessive aversion to doctrinal studies, he argued that both the doctrinal component and the meditative component must be incorporated into a correct version of Buddhism. This led to the creation of his own unique program of “sudden awakening and gradual cultivation.” According to this program, one can clear oneself of secular concerns and arrive at Buddha’s mind only if one comes to be enlightened by meditative insights and at the same time carries out self-cultivation to verify whether what one has understood by enlightenment corresponds to the general truth of Buddhism. This unique theory within the meditation camp became one of the most representative views of Korean Buddhism, influential up to the early twenty-first century.

After Chinul, there emerged a variety of Buddhist philosophies such as purely meditative Buddhism, a Confucian Buddhism, and so on. Still the unique characteristic of Korean Buddhism lies in the fact that it has constantly sought a synthesis of two major traditions of Buddhism, doctrinal tradition and Zen tradition, and it is often argued that Korean Buddhism has been most successful at that. With the formation of the Chosun dynasty, however, Buddhism came to be regarded as something to be overcome and was by and large excluded from ideological pursuits.

### THE ACCEPTANCE OF NEO-CONFUCIANISM

Although it is hard to trace exactly when Confucianism was first introduced to Korea, it is estimated that its introduction accompanied the import of the Chinese writing system roughly around the second century BCE. Koreans began to accept Confucianism as the Three Kingdoms transformed themselves into ancient states and this created a need for Confucian bureaucrats who were versed

in the Chinese writing system well enough to fulfill practical purposes of composing diplomatic documents. Each of the Three Kingdoms had Confucian educational institutions, which produced Confucian scholars and students. From the fact that Confucian virtues such as loyalty and filial piety were prized in the Three Kingdoms, it can be inferred that Confucianism was held in high esteem, even though the scholarship was not up to the level of philosophical analysis.

Confucianism during the Koryo period, as in the Shilla period, was chiefly used as a useful political and practical complement to Buddhism. After the eleventh century, however, as the sovereignty and its administrative structure became stabilized, Confucianism began to distinguish itself from Buddhism. Confucianism that had been only an object of a practical interest began to be the object of serious theoretical research as well. Koryo’s Confucian scholars, represented by Choi Chung (984–1068) and his twelve disciples, considerably advanced the level of Confucian studies as they participated in public administration from the time of King Seong (who ruled from 981 to 997) to King Mun (1046–1083). The private Confucian educational institution Choi founded taught major Confucian Classics. Still, because the program of study was largely oriented toward preparing students for national examinations, it seems that more time was spent on literary exercises than on philosophical investigations.

The later Koryo period was an important time for Confucianism in Korea: This was when Korean Confucian scholars started distancing themselves from Buddhism. Scholars returning from Yuan China brought home with them the Confucianism that was already Yuan’s political ideology, and this transformed Koryo’s Confucianism in a novel way. The Neo-Confucian master Zhu Xi’s writings were introduced in 1289 and numerous Confucian scholars from then on gradually extended the understanding of Confucianism and Neo-Confucianism. A truly novel phenomenon occurring was that these scholars began to mount an attack on Buddhism with philosophical arguments. Yi Saek (1328–1396), one of the last scholars to return from Yuan China, exerted an extensive influence on later Korean Confucians. Even though his own understanding of Neo-Confucianism remained still at a comparatively naive stage in that it simply identified Confucian benevolence with Buddhist compassion, and Confucian repose with Buddhist calmness, Yi Saek produced prominent and influential disciples.

They were trained at the national Confucian educational institution, called Sungkeungwan, which was founded by the government in 1289. They became major figures during the transition period from Koryo to Chosun, which succeeded the Koryo dynasty in 1392. With philosophical explanations of why Buddhism was fundamentally a heresy, they decisively broke with the previous generations of scholars who were largely tolerant of Buddhism. They also played a crucial role in constructing, for the new state, an ideological framework based on Confucianism.

The Chosun dynasty, which replaced the Buddhist Koryo dynasty, adopted Confucian ideology, custom, and order as the political and social foundation of the new state. Those who framed the political philosophical framework for the new dynasty were a group of scholars led by Chung Dojeon. Chung had a leading role in laying the foundation of Chosun's Neo-Confucianism and enabled Confucian ideology to prevail. Because his interpretation of Neo-Confucianism was constructed with a deliberate intention to buttress the new society with a philosophical basis, his philosophy went beyond the personal realm of self-cultivation and moral improvement.

What Chung stressed the most as he propounded Neo-Confucianism was the criticism of Buddhism. He methodically compared the Buddhist worldview with that of Neo-Confucianism, arguing that whereas the basis of the Buddhist worldview was nihilism based on emptiness (*Sunyata*), a robust realism based on *li* and *qi* was the foundation of Neo-Confucianism. *Li* and *qi* are the two most important concepts in Neo-Confucianism. In Zhu Xi's philosophical system, *li*, which is similar to the Platonic idea or the Aristotelian notion of form, is an abstract being. *Li*, like the Buddhist dharma, is often appealed to in the explanation of universal truths governing the natural world and human conduct. *Qi*, on the other hand, corresponds roughly to matter in Western philosophy and it is often invoked to explain the changes in spatiotemporal objects including human bodies and minds. However, *qi* differs from matter as conceived in the West in two important respects. First, Neo-Confucianism locates mind in the domain of *qi*, whereas the Western tradition has tended to regard mind to be distinct from matter. Second, *qi* was construed to be animate, whereas matter is usually construed to be inert and inanimate.

Chung, following the Neo-Confucian tradition, explained the generation and decay of man and nature in terms of *qi* and, on its basis, attacked the Buddhist theory that argued for the illusory nature of the world, the unre-

ality of things, and the transmigration and eternity of the soul. He also attacked the Buddhist doctrine of Karma by claiming that people's differences were not because of what they had done in the past, but because of the *qi* that each person possessed from birth. Chung distinguished Neo-Confucianism from Buddhism in the domain of morality as well. He contended that although the Buddhist notion of compassion had some similarities with the Confucian notion of benevolence, they fundamentally differed in that compassion required treating all beings with indiscriminate equality, whereas benevolence allowed for unequal treatments based on the type of relationship between the benefactor and the recipient. Confucian benevolence, thus construed, served as the fundamental value to sustain the order of the new hierarchical society. Chung's denunciation of Buddhism as a heresy successfully derailed the attempts to revive Buddhism during the early Chosun period and paved the way for other scholars of the upcoming generations to develop and systematize Korean Neo-Confucianism.

The groundwork laid by Chung, however, did not lead immediately to fruitful Confucian research. During the first years of Chosun, a period marked by intense conflicts among the major political factions, Neo-Confucianism as a national ideology lost its initial momentum and was bogged down in exegetical studies. It was during the years of King Sung (1457–1494) that Neo-Confucian scholars returned to hold positions of great influence in the government. Neo-Confucianism began to serve as a practical guide to governance, going beyond its role as a mere ideology. Cho Kwangjo (1482–1519) was the scholar who was most influential in this transition. He claimed that the ruler's moral cultivation was especially important because his moral commitments would exert great influence on the whole nation. Cho urged the view that an ideal Confucian state could be realized through the internalization of Confucian moral values on a national scale and he subsequently led a movement to actualize the view. Views like these were commonly held by the Confucian literati of the time, and it led Neo-Confucians to delve into the nature of human mind and explore the ground and the method of moral practice.

## THE THEORETICAL DEVELOPMENT OF NEO-CONFUCIANISM

Although Neo-Confucianism during the early Chosun period put more emphasis on the practical side, the theoretical side was not completely ignored. For example, the concept of *qi* was exploited to explicate problems such as man and nature, life and death, and the existence of

souls and spirits. The scholar who added depth to the philosophy of *qi* was Seo Kyeongdeok (1489–1546). Seo, classified as a *qi*-philosopher during the early to middle Chosun period, constructed a highly complex and sophisticated theory of cosmology and human nature on the basis of *qi*.

Drawing on the views of Chinese *qi* philosophers during the Song dynasty, in particular Zhang Hengqi and Shao Kangjie, Seo attempted to explain the macroscopic movements and changes in nature in terms of the diverse phases of *qi* and transitions between them. For example, he discriminated between *qi* as a root of everything (pre-celestial *qi*) and *qi* as a changing phenomenon (post-celestial *qi*). Pre-celestial *qi* is the ultimate basis of existing entities, whose movement and change determine variance in post-celestial phenomena. The phenomenal world, which is generated through *qi*'s movements and changes, disappears as *qi* disperses, yet the dispersed *qi* returns again to the pre-celestial realm, which in turn becomes a causal basis of the regeneration of another phenomenal world. Seo associated this cosmology with the principle of Great Change as manifested in the Book of Changes, and applied his theory to the problems of life and death, and even to the question of life after death. His theory of *qi* enabled people to overcome the Daoist concept of nothingness and the Buddhist notion of eternity of the soul; most importantly, it helped the Neo-Confucianism of the Chosun dynasty to gain a unique perspective on man and nature.

The philosophers who completed the framework of Neo-Confucian moral philosophy were Yi Hwang (1501–1570) and Yi I (1536–1584). Yi Hwang, better known by his pen name Toegye, researched in depth the Chinese Neo-Confucian master Zhu Xi, whom he regarded as the ultimate source and authority for Neo-Confucianism. In contrast to Seo before him, he argued that *li* was the ultimate and essential being that determined the movement of *qi*. What particularly concerned Toegye, however, was not the ontology of *li* and *qi* per se, but their roles in grounding morality. He believed that if *li* did not act upon the external world, there would be no ontological ground for morality. In other words, he thought that moral intuition or wisdom would be useless if all human emotions are vulnerable to physical intemperance and overindulgence. It seemed obvious to Toegye, however, that humans had an intellectual control over the mind. From this, he concluded that there must be a domain of emotions that are distinctively moral, and that these must be distinguished from mundane non-moral emotions. He went on to construct the unique view

that everyday nonmoral emotions were manifestations of *qi*, whereas moral emotions were manifestations of *li*. In placing morality within the domain of emotions, Toegye put a greater emphasis on the cultivation of the emotions rather than on purely rational and intellectual training.

Another philosopher who elevated the Chosun dynasty's Neo-Confucianism to another level of sophistication was Yi I (1536–1584), better known by his pen name Yulgok. While revering Toegye's scholarship, he thought that Toegye's dualistic interpretation of Zhu Xi's philosophy had a fundamental problem. Placing a higher value on the aforementioned metaphysical system devised by Seo, Yulgok claimed that although *li* and *qi* were differentiated conceptually, they were not two independent beings. Applying this view to morality, Yulgok maintained that there was no separate source or domain of moral emotions; everyday emotions that conformed to the moral standard were themselves moral emotions. All the emotions including moral emotions were manifestations of *qi*, but they were regulated by *li*. A moral action was not a natural emanation from a separate moral emotion, but the outcome of the recognition of the universal norms and a personal decision to make that recognition bear on the mundane emotions. Because Yulgok considered reason, rather than emotion, to play a central role in living a moral life, he concluded that the enhancement of our rational capacity for right judgments should be emphasized over emotional enrichment.

Weighing between emotion and reason, and between *qi* and *li*, the philosophies of Toegye and Yulgok manifested subtle but significant differences in all respects, leading to two lineages of Neo-Confucianism during the Chosun period. One was *li*-centered and the other *qi*-centered. As the two schools contended for the title of Neo-Confucian orthodoxy, the Chosun dynasty's Neo-Confucianism became increasingly more dogmatic and doctrinaire, leading scholars to the rigid position that all social and individual conduct should conform to the Confucian code of behavior. Leaving behind the metaphysical basis of a moral mind, the debate now moved to another issue over how to apply abstract morality to the real world. Thus, the theory of rites and rituals came to replace the theory of mind, and formed the mainstream philosophy of the seventeenth-century Chosun dynasty.

As the Chosun dynasty's Neo-Confucianism became increasingly more doctrinaire and ritualistic, the chasm between theory and reality, and between philosophy and social development, widened. Scholars, convinced that a blind adherence to Zhu Xi's texts had led them into a dead end, began to search for a breakthrough outside Zhu

Xi. Two trends are notable as consequences of this movement; one was the acceptance of the Chinese Yangming philosophy that recognized the significance of the individual will and freedom. The other was the emergence of exegetical studies that focused on a positivistic interpretation of Confucian Classics free from political ideologies. Scholars involved in these studies hoped to overcome Zhu Xi's philosophy by an appeal to a superior authority (i.e., revered ancient Confucian Classics). The rejection of Zhu Xi's philosophy was significant and it exerted a strong influence on later philosophers, particularly on those belonging to the Practical Study School.

Meanwhile, the scholars from the Yulgok's lineage went on to articulate their philosophical system. In their attempt to refine Yulgok's philosophy, a discordance within his system was discovered, which led to the biggest philosophical debate of the eighteenth century and subsequently caused a split of the school into the *Ho* line and the *Rak* line (*Ho* and *Rak* are names of the regions where their advocates resided). The *Ho-Rak* debate was over the question whether there existed a nature common to both humans and other creatures in the world. The debate that initially started between two scholars gradually widened and came to involve almost all the scholars of the Yulgok school. The debate evolved to cover a wide range of topics such as the relationship between mind and nature, the distinction between the sage and the commoner, and the sameness or difference between human nature and animal nature. In debating over whether there was a general nature common to all things in nature, they came to address the relationship between *li* and *qi* and consequently it provided an opportunity to rethink the status and meaning of *li*. This in turn gave rise to a wide spectrum of thoughts such as the *qi*-only theory and the *li*-only theory.

#### THE RISE OF MODERN THOUGHT— THE INTRODUCTION AND RECEPTION OF WESTERN THOUGHT AND PRACTICAL STUDY

As Korea opened its door to Western thought in the eighteenth century, a notable change in the trend of Korean philosophy took place, and this was the emergence of the Practical Study School. From the early eighteenth century on, the inadequacy of Neo-Confucianism as a political ideology became increasingly more evident. In order to go beyond the limit of Neo-Confucianism and to go along with new social environments, a group of scholars turned their attention from morality and self-cultivation to more practical questions such as economy and the land

system. This trend came to be called Practical Study. Scholars belonging to this movement tried to attain new philosophical insights by blending traditional Neo-Confucianism with newly introduced Western thought, especially Catholicism and Western sciences.

Yi Ik (1681–1763), deeply impressed by the astronomy and the solar calendar brought to Korea by the Christian missionaries, took an active part in introducing Western thought to Korea. He created an atmosphere that enabled his disciples to play leading roles in spreading and promoting Western thought. On the issue of accepting the Catholic doctrine, however, they diverged into a receptive group called the Accept-West Party and a critical group called the Reject-West Party. The latter criticized the fundamental premises of Catholicism including the theory of anima from a Neo-Confucian perspective on the nature of mind. They claimed that Catholicism and Confucianism differed in fundamental assumptions and could not be harmonized with each other.

The Accept-West Party maintained a more open attitude toward Western thought. Among the more influential members of this group was Chong Yakyong (1762–1836), better known by the pen name Dasan, who constructed a comprehensive and influential theory of the Practical Study School, incorporating Catholic theories in his philosophical system. Through a novel reinterpretation of Confucian Classics, not only did he attempt to recover the practical spirit of early Confucianism, but he also tried to synthesize Confucianism and Catholicism. For example, he argued that God in Christianity and Heaven in ancient Confucianism were one and the same; according to him, Heaven in the Confucian tradition was essentially a subject with volitions, desires, and perceptions, and also an agent who used those faculties to rule the universe. Thus, the Confucian Heaven was not to be explicated in terms of metaphysical and abstract principles such as *li* or yin and yang. According to him, then, the term *high-emperor* as employed by ancient Confucians portrayed the meaning of Heaven in the most adequate way, and Heaven, thus construed, was no different from the Christian God.

Dasan also drew on Christian ideas in his explications of morality. Criticizing the Neo-Confucian view that morality was a part of inherent human nature, he maintained that human nature was so constituted as to follow self-regarding desires and preferences and thus it was fundamentally egotistic and hedonistic. He advocated, on this basis, the Christian idea that moral perfection was possible only through recognizing God's will and acting accordingly. Then he attempted to graft Con-

fucianism onto Christianity by adopting the Confucian theory of cultivation as a way of internalizing God's orders. However, such attempts by Dasan and other Accept-West Party scholars caused, among the mainstream scholars who were still committed to Neo-Confucianism as their philosophical idea, a deep sense of insecurity. This played a part in bringing about an official oppression of the Catholic church later, which started in 1785 and lasted on and off for eighty years.

Unlike Yi Ik's disciples who attempted to overcome the limits of Neo-Confucianism by adopting Catholicism, other mainstream scholars in powerful positions embraced Western sciences to improve their Neo-Confucian system. They were called Study-North Scholars, and Hong Daeyong (1731–1783) and Choi Hangi (1803–1877) were the leading figures. Hong, keenly interested in Western sciences, turned his attention from a value-laden Confucian worldview to a morally neutral, positivistic, and scientific worldview. Believing that human existence was on the same level as the existence of any other natural beings, he attempted to explicate everything in terms of *qi*'s movement. Hong's notion of *qi* was similar to today's concept of matter, more so than that of any other *qi*-scholars. *Qi* was, for Hong, a concept suited to cosmology and useful in explaining natural phenomena; he explained the rotation of the earth, tides, and climatic changes by using the concepts such as shrouding *qi*, flowing *qi*, and great *qi*. Thus, in Hong's theory, the dynamic transformations of *qi* were more salient than the ultimate nature of *qi* itself. The significance of Hong's philosophy of *qi* was that it went beyond the Confucian moralist view of the natural world and gave Korean philosophy a modern naturalistic outlook by combining traditional philosophy with the newly introduced Western sciences.

In the case of Choi Hangi, the influence of Western science is even more evident. In Choi's theory, the traditional concept of *qi* played a critical mediating role in assimilating Western scientific theories into his own system. Choi believed that human conduct and natural phenomena were all manifestations of *qi*, and therefore that both Confucian ethics and Western science could be proven to be truths on the same level. Rejecting the Neo-Confucian perspective on morality, he claimed that ethical norms were based on, and derivable from, laws of nature. His *qi*-centered theory not only encompassed existing Confucianism, Buddhism, and Daoism, but could also be harmonized with Western scientific theories.

Two main characteristics of *qi* in Choi's theory were quantifiability and perceivability. Because everything was a manifestation of *qi* and *qi* was perceivable, one could accumulate knowledge only through empirical investigations. According to Choi, the knowledge thus obtained should be able to reach, through verifications and repeated corrections, a level where the fundamental principles common to humans and the natural world could be discovered and natural phenomena scientifically understood. He was also convinced that *qi* could be quantified by numbers. Because the numerical system could reveal changes of *qi* in an objective and general way, scientific studies such as menology (calendar studies), calculus, and physics could reveal the nature of the world most accurately. He even thought that the movement of *qi* could be proven mathematically. What is especially notable in Choi's theory is that Choi had unfettered himself completely from the value-centered, intuition-dependent philosophy of Neo-Confucianism and paved a way to a modern naturalistic way of thinking.

Dasan's Catholic Confucianism, Hong Daeyong's scientific Neo-Confucianism, and Choi Hangi's empirical epistemology were just a few representative attempts, during the eighteenth and nineteenth centuries, to embrace the newly introduced Western thought within traditional philosophy. They had the potential for launching a vital and original philosophical movement. With the fall of the Chosun dynasty, however, these philosophical endeavors did not lead to the formation of modern Korean philosophy. They remained only as one dead-end strand in the history of Korean philosophy.

## MODERN KOREAN PHILOSOPHY

The period from the end of the nineteenth century to the beginning of the twentieth century was a critical turning point for Korea and for Korean philosophy. The Japanese colonialism backed by Western culture and technology began to encroach on Korea. Korea was forced to sign an unequal treaty with Japan in 1876. That provoked other imperialistic countries to coerce similar forms of agreements with Korea. As a result, Korea was defenseless against the tidal influx of Western culture, new languages, and new modes of thinking. Although Korean intellectuals at the time attempted to save Korea from colonization by westernizing Korea itself, it was too little and too late as Korea was annexed by Japan in 1910.

A notable phenomenon that followed was the shift of Korea's and Japan's roles in the transfer of cultures. Traditionally China was the dominant cultural force in the region, and Korea used to import Chinese culture and

incorporate it into its own, and then export the outcome to Japan. By the turn of the century, this pattern of cultural exchanges underwent a dramatic change; the West replaced China and Japan became the conduit of the Western culture to Korea. Even though Korea had earlier contact with Western religion and science, it was only after the Japanese colonization that Korea made its first encounter with Western philosophy. The word *chulhak* was also first introduced to Korea. The word, made up of two Chinese characters, was coined in Japan as a translation of the term *philosophy*, and it is now the standard term for philosophy in the Asian countries in which Chinese characters are used for academic purposes, including China, Korea, and Japan.

That Western philosophy was introduced to Korea through Japanese colonialism, combined with the prevalent picture of Western power and wealth, defined the early perception of Western philosophy in Korea. Philosophy was regarded as something indigenous to the West and completely alien to Korea, having nothing in common with the traditional thought of Korea. In the minds of Korean intellectuals at the turn of the century, the historical dominance of Confucianism was the main reason for Korea's falling behind in the process of modernization. Traditional ways of thinking and Confucianism, in particular, were what had to be overcome, whereas Western culture and philosophy were to be welcomed and assimilated. The introduction of a neologism, *chulhak*, to signify Western philosophy might have reinforced this frame of mind. For example, *Philosophy*, the first academic journal of philosophy published in 1933, contained no article on traditional Korean thought. It took many years to recognize the common features between Western philosophy and Asian thought and to apply the term *chulhak* to both.

Western philosophy was mostly German philosophy. Japan and Germany were allies and the Western philosophy in Japan was for the most part German philosophy. In consequence, Western philosophy introduced to Korea via Japan was also mostly German. Even though Bertrand Russell and John Dewey visited China and Japan respectively in 1910 and 1919 and that these visits aroused the interest of philosophers in Korea, their impact was limited. The dominance of German philosophy in Korea lasted for some time even after Korea's liberation from Japan in 1945, and this continued during the post-World War II years when the influence of German philosophy was diminishing in the rest of the world. Scholars specializing in German philosophy filled the philosophy faculties of the major universities, and they determined the

overall shape and course of the profession until philosophers of a new generation began replacing them.

Writings of Korean philosophers in the early twentieth century were oriented toward practice. Korean philosophers, like any other Korean intellectual at the time, thought of themselves as pioneers of modernization and westernization. Philosophy was supposed to enlighten people and build a new way of thinking. The tendency to highlight the importance of doing philosophy with practical minds, rather than to introduce Western philosophy for its own sake, was manifest in the first issue of the above-mentioned journal, *Philosophy*. The articles published in the first issue included *One Question concerning the Starting Point of Philosophizing*, *What Is Philosophy?: On the Eternity of Philosophy*, *The Idea of an Ethical Evaluation*, and *The Structure of Concrete Existence*. In these articles, the nature of philosophy was defined with an emphasis on its relevance to practice. However, as the Japanese control over academia became ever more strict and rigid, emphases on practice grew weaker.

Korea was liberated from Japan in 1945. However, the country was divided into two Koreas with conflicting ideologies. This led, in 1950, to a calamitous national tragedy, the Korean War (1950–1953). This series of major events left significant marks on the contour of philosophy in Korea. Marxism, which was experimented with and advocated by a scant few philosophers during the Japanese colonial period, blossomed in the midst of the ideological conflicts that followed the liberation. Even though Marxism was soon officially suppressed in South Korea and many influential Marxist philosophers fled to the more hospitable North, Marxism left an indelible impression. Along with Marxism, existentialism emerged as a major player in Korean philosophy. This was mainly due to the Korean War; in particular, French existentialism, born in the ruins and despair of World War II (1939–1945), strongly resonated with Koreans with similar experiences during the Korean war.

A long-standing bias toward German philosophy began to change in the early 1950s. The Korean Philosophical Association was formed in 1953, and its official journal was founded. More important was that Korea started having direct contacts with Western philosophies. Philosophers came to visit Korea from the United States, Great Britain, and Germany. Students went to various parts of the world for studies. By having direct contacts, Korean philosophers gained firsthand access to Western philosophy, helping them to overcome the distortions inflicted by Japanese translations and interpretations.

Another outcome of this direct and broad exposure to Western philosophy has been the revival of interest in traditional philosophy. Ever-expanding contacts with diverse cultures and philosophies made Korean philosophers rethink the roots and identity of Korean thought. Traditional Korean philosophy, which had been ignored as useless and retrogressive during the Japanese colonial period, began to receive fresh scrutiny and assessment. In the late 1950s, Korean traditional thought came to be accommodated under the umbrella of philosophy.

As a result of interaction with diverse parts of the world, different trends of philosophy are evenly reflected in Korean philosophy today. Anglo-American analytic philosophy is one of the strongest trends. German philosophy is still going strong even though it is not as prominent as it once was. Many philosophers in Korea specialize in traditional Korean philosophy and other Asian philosophies. The world of philosophy in Korea is a melting pot. A large variety of traditions and trends are actively and vigorously represented—from phenomenology and existentialism to analytic philosophy, Buddhism, and Confucianism. Now philosophers pursuing diverse perspectives are starting to hold dialogues with each other. It is exciting to wait and see whether and how the world of philosophy in Korea will continue its tradition of integrationism and what the outcome will be.

## KORN, ALEJANDRO (1860–1936)

Alejandro Korn, an Argentine metaphysician and ethical philosopher, was born in San Vicente. He took his doctorate in medicine and directed a hospital for the mentally ill. In 1906 he joined the faculty of philosophy and letters at Buenos Aires. Although he wrote little, he had immense personal influence on Argentine philosophy. His philosophical writing came late in his life: *La libertad creadora* (La Plata, 1930), his major work, is a compilation of five essays dating from 1918 to 1930.

Korn is sometimes called a positivist, a label suggested by his scientific training, his empiricism, the skeptical note in his metaphysics, and his ethical relativism. However, his “Incipit Vita Nova” (1918) set the stage for his own criticism of positivism. In this essay, he maintained that despite the scientific and technological progress of preceding decades, contemporary man is dissatisfied and disillusioned. The cause is the impairment of ethics by the spread of the positivistic doctrine that man is a machine without liberty; the remedy is a libertarian philosophy that subordinates science to ethics. Korn’s sources were not Auguste Comte or Herbert Spencer, but Henri Bergson, Arthur Schopenhauer, and Immanuel Kant.

Korn’s methodology rests on an experiential intuition whose objects are concrete particulars of ordinary experience. This common intuition is not passive and its content is not simple. Reason supplies concepts that are merely formal and symbolic but that penetrate intuition; the latter always has discursive elements. There is also a more intimate intuition or vision, which has intellectual, mystical, and aesthetic forms corresponding to metaphysics, religion, and art. Intuition as vision suggests pro-

found convictions and has an important place in the spiritual life of man, but it carries no assurance of truth. For comparative certainty we must turn to the two disciplines of ordinary intuition: science, which has a measurable object in the external world of fact, and axiology, which has an unmeasurable object in the internal world of evaluation. The third great intellectual enterprise, metaphysics, attempts to describe reality through concepts that transcend all possible experience. Metaphysical systems are dialectical poems. We cannot live without metaphysics, but we cannot convert it into a science; it should contain sincere convictions, free from dogmatism.

The external world of science, of the not-self, known through sensations, is spatial, measurable, and governed by strict causal law. The internal world of axiology, of the self, constituted of emotions, volitions, and judgments, is nonspatial, immeasurable, purposive, and free. These are the two halves of one encompassing domain of consciousness, which comprises all that we know and, it seems, all that is real. Common to both halves of consciousness are three further characters: activity or perpetual becoming, which shows that stable things and rigid names are false; relativity, which expresses the fact that every particular act has its reason in another; and time. Most significant in distinguishing the subjective from the objective order is freedom: economic freedom, or mastery of the external world, and ethical freedom, or mastery of self.

The search for an ultimate reality beyond consciousness led Korn to deny monistic realism, dualistic realism, and solipsism, and to affirm a type of absolute idealism. Experienced things, space, and time depend on consciousness, evidently because they involve organizing concepts or forms. A thing lying beyond consciousness and implied as cause of the experienced thing is denied: causality is a creature of our thought. The known object thus depends on consciousness and has its being there. But that does not entail the dependence of objects on my self. The self, or subjective order, is only a part of consciousness; it is not the source of the known world. The further definition of this idealism is through the theory of the *acción consciente*: consciousness as an everlasting, dynamic, and creative process, unknown in itself but manifested as aspiration toward absolute liberty.

This ontological goal is the key to Korn's theory of values. A value is the created object of an affirmative valuation, and valuation is the reaction of the human will to an event. Values therefore are subjective. There are instinctive, erotic, vital, economic, social, religious, ethical, logical, and aesthetic values, none of which can be reduced to any other. Values achieve unity through their

common source in human personality and through their common goal in the liberty of man. Creative liberty is the recurring motif of Korn's philosophy.

## KOTARBIŃSKI, TADEUSZ (1886–1981)

Tadeusz Kotarbiński, a Polish philosopher and logician, was born in Warsaw in 1886. He studied philosophy and the classics at the University of Lvov, where he obtained his doctorate in 1912. He began teaching at the University of Warsaw in 1918 and soon became perhaps the most influential philosophy teacher in Poland. His enlightened views, integrity, public spirit, and social zeal frequently brought him into conflict with established opinions and with the government, both before and after World War II. Admired by many and respected by all, Kotarbiński commanded a unique position of moral and intellectual prestige in his country. He was a member of the Polish Academy of Science and of the International Institute of Philosophy, and he was for a long time chairman of both bodies. He held an honorary doctorate from the Université Libre in Brussels and was a corresponding fellow of the British Academy and an honorary member of the Academy of Sciences of the U.S.S.R. and of other foreign scientific organizations.

### CONCRETISM

Kotarbiński began his philosophical career as a minimalist. He advocated the abandonment of such terms as *philosophy* and *philosopher* because of their ambiguity and vagueness. The miscellaneous collection of subjects traditionally known as philosophy lacks any factual or logical coherence. These various subjects should be reconstructed as specialized fields of study and thus acquire some recognized criteria of professional competence. "The philosopher" should mean "the teacher of philosophy," and "philosophy" should be used restrictively to

denote moral philosophy and logic in the broad sense, which comprises formal logic, the philosophy of language, the methodology of science, and the theory of knowledge. Kotarbiński himself chose logic in this broad sense as the chief subject of his own concern. He wished to transform logic into a science as exact as mathematical logic and he applied himself to the construction of the conceptual apparatus necessary for this task. However, the results of this analytical work, accomplished between 1920 and 1935, exceeded the original design and produced a system known as reism or concretism. Kotarbiński regarded it as a program rather than a set doctrine and for linguistic reasons preferred *concretism* to *reism*.

Concretism arose from the puzzle about how qualities can belong to or inhere in the things of which they are characteristics. Kotarbiński believed that the puzzle can be resolved if we recognize that whereas things may be hard or soft, black or white, and so forth, nothing is hardness or softness, blackness or whiteness. Thus, the insight underlying concretism can be expressed in the proposition “only concrete individual objects exist.” The expression “*a* exists” has the same meaning as “something is an *a*” (ex  $a =_{\text{df}} (\exists x) x \text{ is } a$ ) and the meaning of *is* can be explicated as follows:

$$(a, b) :: a \in b \equiv \therefore (\exists x) . x \in a \therefore (x) : x \in a \supset . x \in b \therefore (x, y) : x \in a . y \in a \supset . x \in y.$$

This theorem is an early formulation of the single axiom of Leśniewski’s ontology and should be read as an implicit definition of the functor “is” in expressions of the type “*a* is *b*,” in which “is” has its main existential meaning.

**SEMANTIC REISM.** Concretism is both a metaphysical and a semantic doctrine; as metaphysics its basic characteristic is materialism and as semantics it is nominalism. Nominalism is an essential part of concretism, but materialism is not. For instance, Franz Brentano, although a concretist, was a Cartesian dualist.

If the dyadic functor “is” in expressions of the type “*a* is *b*” has the meaning defined above, then only genuine, empty or nonempty, shared or unshared names are admissible values for *a*. This should be clear in view of the fact that if *a* is *b*, then for some *x*, *x* is *a*, that is, *a* exists (therefore, if an empty name is substituted for *a*, “*a* is *b*” always becomes a false sentence). Semantic reism is a set of linguistic and logical rules that allow us to test the meaningfulness and truth of the expressions of language *L* as determined by their syntactic structure and semantic function.

According to semantic reism, names of concrete objects only, either corporeal or sentient, are genuine names. The names of properties, relations, events, facts, propositions, or classes are objectless and apparent names. Literally understood, sentences involving such fictitious names and implying the existence of properties, relations, events, facts, propositions, or classes are grammatically meaningful expressions, but reistically they are nonsense in disguise or falsehood. Only if, by a suitable transformation, such sentences can be reduced to equivalent expressions involving no apparent names can they become reistically meaningful and either true or false. For instance, in its literal meaning the sentence “the relation *being part of* is transitive” is either false or nonsensical. But if it is regarded as a shorthand statement of the fact that for all *x*, *y*, and *z*, if *x* is part of *y* and *y* is part of *z*, then *x* is part of *z*, the expanded version of this abbreviated sentence expresses a genuine and true proposition.

**ONTOLOGICAL REISM.** Nominalism is the view that the only admissible values for bound variables are entities of the lowest type as understood in the simplified theory of types. To apply this assumption outside logic and mathematics we need operational rules specifying the entities of the lowest type, that is, the referents of genuine names. For this purpose semantic reism must be supplemented by ontological reism; in other words, one’s metaphysical commitments must be explicitly stated.

The basic proposition of ontological reism states that every object is a thing. *Object* is the most general ontological term, synonymous with *something*, the name of an arbitrarily chosen thing and thus extensionally equivalent to *thing*. *Thing* is a defined term and means a physical or a sentient body, in the nonexclusive meaning of *or*. *Physical* means spatial, temporal, and resistant, and *sentient* is defined by the Socratic definition as a term appropriately qualifying such bodies as animals or human beings (and probably also plants). Kotarbiński described ontological reism as somatism rather than as materialism, because for a reist “matter” is an apparent, quasi name, unless it is defined as a metatheoretical concept, in terms of which we speak about material or physical objects identified by the attributes of spatiality, temporality, and resistance and not by material substance. But somatism entails pansomatism, the proposition that every soul or mind (sentient entity) is a body. Therefore, a concretist who accepts pansomatism and asserts that there are only bodies in the universe is a materialist in the sense that he subscribes, speaking loosely, to the identity theory of mind and body. He leaves it to science to discover how it came about that there are sentient as well as physical bodies in the world.

In the theory of knowledge concretism implies the abandonment of the epistemological dualism of the theory of representative perception and the adherence to some form of sensational realism. Since there are no mental images or elements or sense data distinct from the object perceived, a concretist believes that all that is known is apprehended directly and that the so-called perceptual content is part of the physical object.

**IMITATIONISM.** If reality consists exclusively of bodies, and if the soul or mind is identical with part or the entire organism of a human individual, assertions about mental states and processes are not semantically well-formed sentences; they are objectionable on ontological grounds and consequently false. To be realistically acceptable they must be regarded as assertions of special sorts about persons, reducible, when fully stated, to descriptions of human individuals acting upon their environment and being affected by the external world. This view of the nature of psychological statements, together with the procedure by means of which they can be reduced to statements about persons doing and undergoing things, Kotarbiński called “imitationism.” This name is intended to indicate that we come to understand the experiences of other people by imitating their behavior and, in general, that psychological knowledge is acquired not from introspection but by imitation or self-imitation.

Imitationism assumes that every singular psychological statement is a substitution of the schema “*A* experiences this: *P*,” where *A* is a proper-name variable and *P* is a variable admitting all kinds of enunciations referring to the physical environment of the person whose name is substituted for *A*. The first part of the schema is the announcement by the experiencing person, *EP*, or the observer, *O*, of what its second part expresses by describing the environment in the same way that *EP* describes or would describe it. If *EP* and *O* are two different persons, the announcement refers to the imitation of *EP* by *O* and mentions the respect in which *EP* will be imitated. If *EP* and *O* are the same person, imitation becomes self-imitation and the description of the environment, including *EP*’s own body, is self-description.

## PRACTICAL PHILOSOPHY

Kotarbiński had a lasting interest in practical philosophy. He saw its main task as the formulation of precepts and recommendations concerning the three questions of how to achieve happiness, how to live a good life, and how to act effectively. It is the second and third set of questions to which he devoted most attention. He was a staunch

defender of the autonomy of ethics and approached its problems deontologically. Inspired both by a theoretical interest and by the desire to help his fellow men, he produced a general theory of efficient action known as praxeology. Although he had some predecessors, in particular A. A. Bogdanov (1873–1928) and Georges Hostelet (1875–1960), he accomplished pioneer work and opened a new field of study.

Z. A. Jordan (1967)

## KOZLOV, ALEKSEI ALEKSANDROVICH (1831–1901)

Aleksei Aleksandrovich Kozlov, the Russian personalist philosopher, was the first major Russian exponent of a pluralistic idealism derived from Gottfried Wilhelm Leibniz. In his youth Kozlov studied the social sciences and was attracted to the ideas of Ludwig Feuerbach and François Marie Charles Fourier. His socialist views led to a short prison term in 1866 and the loss of his teaching position in a Moscow secondary school. He began to study philosophy seriously only in the 1870s, when, after an initial interest in materialism, he came successively under the influence of Arthur Schopenhauer, Eduard von Hartmann, and Immanuel Kant. In 1876 he became professor of philosophy at Kiev University, where he published the first Russian philosophical journal, *Filosofskii trekhmesiachnik* (Philosophical quarterly), and began to formulate his own mature position under the influence of Leibniz and his followers—notably Gustav Teichmüller. When illness forced Kozlov to retire in 1887, he moved to St. Petersburg and expounded his views systematically in

a private journal, *Svoe slovo* (A personal word), published occasionally from 1888 to 1898.

In Kozlov's metaphysics, which he called panpsychism, there is a plurality of conscious spiritual substances, or monads. Each is an agent whose being consists not only in its substantiality, but also in its (psychic) activities and the contents of these activities. (Thus, Parmenides erred by considering substance alone, Johann Gottlieb Fichte by considering activity alone, and other philosophers erred similarly.) Together, these spiritual substances form a closed totality which is grounded in a Supreme Substance, God, and within which these substances (unlike Leibniz's monads) interact. The human body is a collection of less conscious spiritual substances with which our ego interacts until death. Kozlov suggested that after death the ego is reincarnated by interacting with other spiritual substances to form a new body.

The "material" aspect of the body, as of all supposed "material" entities, is produced by thought in our interaction with other spiritual substances, and is symbolic of these substances. Space and time (to which Kozlov devoted much attention) are likewise products of the thinking subject. Neither is objectively real, but each is symbolic of reality: Space is symbolic of the fact that real substances exist in connection, and time of the fact that within this connection there is variety and activity. Thus sense perception, which purports to show us objects in space and time, does not penetrate to the essentially timeless and spiritual reality. Kozlov developed an intuitionist epistemology, in which knowledge is based upon "primitive consciousness"—primarily consciousness of one's own ego. Primitive consciousness, however, being simple and immediate, is nonconceptual and ineffable. Knowledge, on the other hand, is complex and mediated; the mind constructs it by relating the elements of primitive consciousness. Thus we are directly conscious of God. Acquiring conceptual knowledge of God, however, is a difficult intellectual enterprise.

Kozlov did not develop his views fully in other areas, but his metaphysics and epistemology influenced many Russian philosophers, including his son, Sergei A. Askoldov, and Nikolai Losskii.

## KRAUSE, KARL CHRISTIAN FRIEDRICH (1781–1832)

Karl Christian Friedrich Krause, a German pantheistic philosopher, was born at Eisenberg in Thuringia. He studied at Jena, where he came under the influence of Johann Gottlieb Fichte and Friedrich Schelling. In 1812 he became Privatdozent, but his many efforts to secure a professorship were all unsuccessful. For a time he taught music in Dresden. In 1805 he joined the Freemasons, to further his ideal of a world society. His internationalist leanings were responsible for his failure to be appointed professor in Göttingen, and in Munich his chances were spoiled by the opposition of Schelling. Just as he finally obtained a position, Krause died of a heart attack.

Like several of his contemporaries, Krause claimed to be developing the true Kantian position. His orientation, however, was mystical and spiritualistic. The obscurity of his style is awesome; he expressed himself in an artificial and often unfathomable vocabulary which included such monstrous neologisms as *Or-om-wesenlebverhaltheit* and *Vereinselbganzweseninnesen*—words that are untranslatable into German, let alone into English. He called his system the theory of essence (*Wesenlehre*) and presented an elaborate set of categories, including Unity, Selfhood, Propositionality (*Satzheit*), "Graspness" (*Fassheit*), Unification-in-propositionality (*Satzheitvereinheit*), and so forth. The system was intended to mediate between pantheism and theism; hence Krause called his position "Pantheism," to suggest the idea that God or Absolute Being is one with the world, though not exhausted by it. From this central doctrine Krause derived a theory of man and of history. He regarded all men as part of a spiritual whole, an ideal League of Humanity (*Menschheitsbund*), the actualization of which is the goal of history.

Like Fichte, Krause took self-consciousness as his starting point in the belief that it provides a key to the

essence of all things. The ego discovers itself to be both mind and body, enduring and changing; it is an organic, self-sustaining whole. According to Krause, this is the clue to the nature of other beings and of God. Considering its own finitude and that of other beings it encounters, the ego is led to the idea of an absolute, unconditioned principle upon which it and all other creatures and organizations are dependent. This principle is God, or Essence, whose nature is grasped in a spiritual intuition (*geistigen Schauen*), an immediately certain vision that is the foundation for all subsequent knowledge. God is primordial being (*Orwesen*), the being without contrareity; he is the unity of all that exists. Though he contains the world, he is nevertheless other than and superior to it. The distinction between God and the world is that of whole and part. Krause expressed this by speaking of God as *in himself* Contrabeing (*Gegenwesen*) and Unified Being (*Vereinwesen*), while *as himself*, or qua Primordial Being, he is absolute identity.

The existence of the world follows from an inner opposition in God's actuality (*Wesenheit*). Reason and Nature are two subordinate beings distinguished from, and yet lying within, God. Humanity is a synthesis of these. Humanity and the world, along with numerous basic human institutions, are organisms through which the divine life expresses itself. Thus, every being or group of beings is godlike in essence. Mind and body are integrated in the particular unified being that is man, reflecting the compresence of Reason and Nature in all things. Nature composes all individuals into a single whole. It is a mistake to view nature as a blind, mechanical system without consciousness; for its infinite perpetual activity, which is a pure self-determination, is free. Nature is a divine work of art; at the same time it is itself the artist, fashioning itself. The recognition of this divine character gives meaning and value to life.

Individual human minds together constitute the realm of Reason throughout which mind is organically distributed. But mind does not exist only in man and his institutions. Nature and Reason interpenetrate so fully that even animals are a unification of the two. Among animals, however, the career of each is fixed inexorably, according to the hierarchy of living forms. Man is the supreme unification of Reason and Nature, for he possesses the highest sort of mind joined to the highest sort of body. The individual souls that make up humanity are eternal, uncreated, immortal. Their number can neither be increased nor diminished. Humanity is thus complete at every moment.

What men should strive for is the imitation of the divine life in their own inner lives and in their social organizations. God is good, and men should participate in this goodness. The inner union with God (*Gottesinnigkeit*), or fervor for the divine, is the foundation of ethics, and ethics is the heart of religion. But individuals cannot achieve the moral life alone, since they are what they are only as parts of the whole. The community and its various institutions are thus indispensable.

Ideally, the community is governed by Right, which Krause defined as the organic whole of all of the internal and external conditions necessary for the completion of life that are dependent on freedom. This supernatural law is grounded in the nature of the divine; it expresses the right of Humanity, not simply the right of individual human beings. The rights of individuals, groups, and nations can be recognized, but only as subordinate to the right of Humanity as a whole. Humanity is divided into a series of social organisms. There are, Krause speculated, human inhabitants in many cosmic systems. These human beings are subdivided into nations, races, communities, families, and so forth. There is an aesthetic community, a scientific community, a religious community, and a moral community. Each community has rights, although the right of Humanity takes precedence.

Men are all citizens of the universe, which is an infinite divine government. Because he revered the individual as a partial embodiment of the divine, Krause argued against the death penalty and maintained that punishment can be justified only as educative and reformatory. Only a republican form of government, he believed, is entirely compatible with the ideal of justice.

According to Krause's philosophy of history, the development of humanity is the temporal unfolding of a moral ideal. History follows a three-stage pattern, which is mirrored in every individual life as well. The development is not, however, purely progressive. There are two orders, one "ascending" and one "descending," so that the divine life may be presented again and again in the infinitely repeated epochs of history. The three steps in the ascending order are Wholeness, Selfhood, and Wholly-unified-selfhood. In the stage of Wholeness, each individual or higher organism exists germinally in the larger whole to which it belongs. In Selfhood, it enters into a free opposition to that whole and strives to develop its unique character. Evil appears as the individual organism tears itself loose from the harmony of the whole. Finally, the organism achieves a loving reunion with other beings (man, for example, becomes reunited with Nature, Reason, Humanity, and God), and with this rediscovery of

harmony, all evil is negated. Afterward, however, the historical path leads downward, to a final involution that is both the ending of a career and the birth of a new life. Since the transition is gradual, an older age may survive for a time in a newer age. Each development, nevertheless, exhibits genuine, unforeseeable novelty.

Following this order, the individual man enters the world, proceeds through the stages of embryonic life, boyhood, and youth, and becomes increasingly independent, until he finally achieves the maturity of manhood, from which point he descends in a reverse series. Every human institution and organization pursues the same course of evolution, reflecting the basic laws of the divine organic life. In history, the first stage is marked by polytheism, slavery, caste systems, despotic governments, and a state of war between peoples. In the second period, the age of growth, men recognize the divine as an infinite being standing above all that is finite. This is monotheism, which Krause accuses of fostering theocracy, religious censorship of science and art, and contempt for the world. Finally, in the third stage (to which Krause's own philosophy is supposed to inspire men), humanity comes of age, the finite is reunited with the infinite, and world citizenship, philanthropy, and tolerance become the rule. According to Krause, the transition to this stage began with Benedict de Spinoza's discovery of the nature of being, and his own system was to be the development of that theory. He envisaged humanity as arriving at an organic completeness that represents the maturity of the race, and with visionary eloquence he depicted the unification of all humankind, as all men and all associations of men enter into a common life.

Krause's philosophy, while not very influential in Germany, found considerable support in Spain, where, for a time, "Krausism" flourished. This was largely due to the efforts of Julian Sanz del Rio, the minister of culture, who visited Germany and Belgium in 1844 and came into contact with a number of Krause's disciples, notably Heinrich Ahrens in Brussels and Hermann von Leonhardi in Heidelberg.

### **Bibliography**

Krause's most important work is *Das Urbild der Menschheit* (Dresden, 1812), translated into Spanish by Sanz del Rio as *El ideal de la humanidad* (Madrid, 1860). Included among his other works are *System der Sittenlehre* (Leipzig, 1810);

*Vorlesungen über das System der Philosophie* (Göttingen, 1828); and the short *Abriss des Systems der Rechtsphilosophie* (Göttingen, 1828).

For Krause's influence in Spain, see Sanz del Rio, K. C. F. *Krause: lecciones sobre el sistema de la filosofia analitica* (Madrid, 1850) and Juan Lopez Morillas, *El Krausismo español* (Mexico City, 1956). See also Hans Flasche, "Studie zu K. C. F. Krauses Philosophie in Spanien," in *Deutsche Vierteljahrsschrift für Literaturwissenschaft und Geistesgeschichte* 14 (1936): 382–397. Flasche mentions the "left" and "right" wing of Krausism in Spain and, to account for Krause's success in Spain, tries to show (with a tenuous argument) the compatibility of Krause's views with Catholicism. Sharply critical of Krause is Eduard von Hartmann, "Krause's Aesthetik," in *Zeitschrift für Philosophie und philosophische Kritik* 86 (1) (1885): 112–130. Sympathetic accounts of Krause are to be found in Paul Hohfeld, *Die Krause'sche Philosophie* (Jena: H. Costenoble, 1879) and Rudolf Eucken, *Zur Erinnerung an K. Ch. Krause* (Leipzig, 1881). (Hohfeld edited a number of Krause's works, and Eucken studied with a student of Krause.) Clay Macauley, *K. C. F. Krause, Heroic Pioneer for Thought and Life* (Berkeley, CA, 1925) is a eulogistic pamphlet.

## KRIPKE, SAUL

(1940–)

Saul Kripke is an American logician and philosopher born in New York in 1940. After earning a BA from Harvard University in 1962, he held positions at Harvard, Rockefeller, Princeton, New York Universities, and elsewhere.

### MODAL LOGIC

Saul Kripke has worked in many branches of logic (higher recursion theory, set theory, models of arithmetic, and relevance logic), but the work best known to philosophers, and much cited in the literature of linguistic semantics, computer science, and other disciplines, is his development of Kripke models for modal and related logics. At the level of sentential logic such a model consists of a set  $X$  (of "states of the world," often misleadingly called "worlds"), a binary relation  $R$  (of "relative possibility") thereon, plus an assignment to each atomic formula  $p$  of the set of those  $x$  in  $X$  at which  $p$  is true. The assignment extends to all formulas, taking "Necessarily  $A$ " to be true at  $x$  if  $A$  is true at every  $y$  with  $xRy$ .

Kripke was the first to publish proofs of completeness theorems to the effect that truth at all  $x$  in all models with  $R$  reflexive (and transitive) (and symmetric) coincides with provability in the modal logic **T** (respec-

tively **S4**) (respectively **S5**), and he obtained similar results for other modal logics. Announced in "Semantic Considerations on Modal Logic" (1963), and presented in detail in a subsequent series of technical papers, Kripke's work covers modal and intuitionistic sentential and predicate logic, and includes besides completeness theorems results on decidability and undecidability.

### SEMANTIC PARADOXES

Also well known is Kripke's work on semantic paradoxes in "Outline of a Theory of Truth" (1975). A truth-predicate in a language  $L$  permitting quotation or equivalent means of self-reference would be a predicate  $T$  such that the following biconditional holds with any sentence of  $L$  in the blanks:

" $T$ (                  )" is true if and only if "                  " is true.

The liar paradox shows there cannot be a truth-predicate in  $L$  if  $L$  has no truth-value gaps. Given a partial interpretation  $I$  of a predicate  $U$  (under which  $U$  is declared true of some items, declared false of others, or not declared either of the rest), any treatment of truth-value gaps, such as Stephen Cole Kleene's three-valued or Bas van Fraassen's supervaluational approach, will dictate which sentences containing  $U$  are to be declared true, declared false, or not declared either. If  $U$  is being thought of as "is true," this amounts to dictating a new partial interpretation  $I^*$  of  $U$ . For a fixed point, or partial interpretation having  $I = I^*$ , the biconditional displayed earlier holds.

Kripke's work, besides more purely philosophical contributions, shows how to obtain a minimal fixed point (contained in any other, and explicating an intuitive notion of *groundedness*), a maximal intrinsic fixed point (not declaring true anything declared false by any other fixed point), and many others, for any reasonable treatments of gaps.

### WITTGENSTEIN AND SKEPTICISM

Turning from logic to philosophy of language and its applications to analytic metaphysics, Kripke has written two much-discussed books that are almost entirely independent of each other. In *Wittgenstein on Rules and Private Language* (1982) he advances as noteworthy, though not as sound, an argument inspired by his reading of Ludwig Wittgenstein's *Philosophical Investigations* (1953/1993) that is not unqualifiedly attributed to Wittgenstein. On Kripke's reading the target of the argument is any theory (such as that of the *Tractatus Logico-Philosophicus*) that conceives of meaning as given by

conditions for truth, conceived as correspondence with facts. Kripke compares Wittgenstein as he reads him to David Hume (more specifically, to a version of Hume that takes seriously his protestations that he is only a mitigated, not an extreme skeptic). So read, Wittgenstein's attack on correspondence theories of meaning consists, like Hume's attack on rationalist theories of inference, of two phases.

First there is a "skeptical paradox." Consider an ascription of meaning, say that according to which by "plus" I mean *plus*, so that 125 is the right answer to the question "what is 68 plus 57?" as I mean it. To what fact does this correspond? Not the record of how I have worked sums in the past. (Perhaps I have never worked this one before, and many rules are compatible with all the ones I have worked so far.) Not my ability to state general rules for doing sums, since this only raises the question what fact corresponds to my meaning what I do by the words in these rules. Not my behavioral dispositions (nor anything in the structure or functioning of my brain causally underlying them) since what answer I am *disposed* to give is one question, and what answer would be the *right* one for me to give is another question; and I am disposed to give wrong answers fairly often even for medium-sized numbers, and to give no answer at all for really big ones. Further considerations rule out also introspectable feelings accompanying calculation. No candidates seem to remain, so it seems that there is *no* fact to which an ascription of meaning corresponds. The conclusion is that *if* meaning consists in conditions for truth and truth of correspondence with facts, *then* ascriptions of meaning like "What I mean by 'plus' is *plus*" are neither true nor meaningful, and no one ever means anything by anything.

Second, there is a "skeptical solution," defying short summary. This solution identifies the meaningfulness of a sentence with the possession *not* of truth-conditions but of a potential for use within a speech community. The aspects of use—of usage and utility—that are emphasized are on the one hand the conditions under which assertion of a sentence is warranted, and on the other hand the applications warranted when a sentence is accepted.

One objection, anticipated by Kripke, is that Wittgenstein does accept talk of "truth" and "facts" in a deflated sense, in which sense to say, "It is true or a fact that by 'plus' I mean *plus*," amounts to no more than saying, "By 'plus' I mean *plus*," which on Kripke's reading Wittgenstein never denies. So a straightforward statement of Wittgenstein's view as the thesis that there are no

"facts" corresponding to meaning ascriptions will not do. But as Kripke notes, one of the tasks of a reading of Wittgenstein is precisely to explain why he does *not* state his view in straightforward philosophical theses. Other objections to Kripke's interpretation, which has Wittgenstein opposing one theory of meaning to another, have been advanced by those who interpret Wittgenstein as a "therapist" who aims to treat philosophical questions not by developing philosophical theories (of meaning or of anything else) to answer these questions, but by developing methods to cure one of wanting to ask such questions. But such a reading may be less utterly irreconcilable with the reading of Wittgenstein as skeptic than its proponents generally recognize, since after all historical skepticism was itself a form of psychotherapy, aiming to achieve philosophic *ataraxia* by cultivating indifference to unanswerable questions.

## REFERENCE AND METAPHYSICS

Kripke's most famous work is *Naming and Necessity* (1980), which consists of a transcription (with addenda and a preface written a decade later) of lectures given at Princeton in 1970. Only a rough, brief treatment will be possible here, leaving entirely to one side the influential ancillary papers "Speaker's Reference and Semantic Reference" and "A Puzzle about Belief," related work of Keith Donnellan (on proper names) and Hilary Putnam (on natural kind terms), and Kripke's provocative discussion of several side topics (among them the contingent *a priori* and the identity theory in philosophy of mind).

Kripke maintains the following doctrines about naming, illustrating them with examples, many of which have become famous. The reference of a proper name (e.g. "Phosphorus," "Feynman," "Newton") is *not* determined by some associated definite description (or cluster of descriptions, which is to say, description of the form "the object of which *most* of the following is true ..."). The description a speaker associates with a name may be incorrect. (The speaker may describe Isaac Newton as "the man who was hit on the head by an apple and thereby struck with the idea of a force of gravity.") Even if correct, it may fail to be uniquely identifying. (The speaker may be able to describe Richard Feynman [1918–1988] only as "a famous physicist," which does not distinguish him from Murray Gell-Man [1929–].) Even if correct and uniquely identifying, it may be so only contingently, so that in speaking of certain counterfactual situations the description may denote something else or nothing at all. (Phosphorus, though it *is* the brightest object regularly visible in the eastern sky before sunrise,

might have only been second brightest, in which case “the brightest ...” would have denoted something else; while if it had been tied for brightest, “*the* brightest ...” would denote nothing.) By contrast, names designate rigidly, continuing to designate the same thing even when discussing counterfactual hypotheses. (If I say, “If there had been a brighter object, Phosphorus would have been only second brightest,” I am still speaking of *Phosphorus*.)

A better picture than the description theory of how a name comes to denote its bearer would be this: The first user of the proper name or “initial baptist” may fix its reference by some description (possibly involving demonstratives and requiring supplementation by ostension, for example, “that bright object over there by the eastern horizon”). The second user may use the name with the intention of referring to whatever the first user was referring to, while perhaps ignorant of the original description. And so on in a historical chain. (Some commentators say causal chain, but it is important to note that there need not be any causal connection between initial baptist and thing named, which may be a mathematical object.) Kripke also offers an analogous picture of how a natural kind term comes to denote the kind of things it does.

Kripke also maintains the following doctrines about necessity, partly as corollaries to the above doctrines about naming. A true identity linking proper names (e.g., “Hesperus is Phosphorus”) is necessary (as a consequence of rigidity, since even in a counterfactual situation each name will continue to denote the bearer it actually denotes, and therefore the two will continue to denote the *same* object, if they actually do so). But such an identity is not *a priori* (the identity of the heavenly body spotted at dawn and called “Phosphorus” with the one seen at dusk and dubbed “Hesperus” being an empirical astronomical discovery). Therefore, the metaphysical notion of necessity, “what could not have been otherwise,” must be distinguished from epistemological notions like “what can be known *a priori* to be so.”

There are other examples of metaphysical necessities, many involving natural kind terms: the facts of identity of heat with random molecular motion, of water with H<sub>2</sub>O, of gold with the element of atomic number 79, and more; that a given object (e.g., a table) is composed of the material it is composed of (wood rather than ice); that a given person or organism has the ancestry he, she, or it does (e.g., that Elizabeth II is the daughter of George VI, and if he had had no daughter, she would never have been born). This is so even though in none of these examples does one have *a priori* knowledge. (There would be no

internal logical contradiction in a tabloid press article claiming Elizabeth II to be the daughter of Harry Truman.) Historically, from Immanuel Kant to Gottlob Frege to Rudolf Carnap and beyond, necessity had tended to dwindle to aprioricity, which in turn had tended to dwindle to analyticity; Kripke’s sharp reversal of this trend is perhaps his most important single contribution to philosophy.

## KRISTEVA, JULIA

(1941–)

Julia Kristeva was born on June 24, 1941, in Sliven, Bulgaria. She was educated by French nuns, studied literature, and worked as a journalist before going to Paris in 1966 to do graduate work with Lucien Goldmann and Roland Barthes. While in Paris she finished her doctorate, was appointed to the faculty of the Department of Texts and Documents at the University of Paris VI (Denis Diderot) and began psychoanalytic training. Currently, Kristeva is Director of the Department of Science of Texts and Documents at the University of Paris VII, where she teaches in the Department of Literature and Humanities.

In her early writing, Kristeva is concerned with bringing the speaking body back into phenomenology and linguistics. In order to counteract what she sees as the necrophilia of phenomenology and structural linguistics,

which study a dead or silent body, Kristeva develops a new science that she calls *semanalysis*. She describes semanalysis as a combination of semiology (or Semiotics) from Ferdinand de Saussure, and psychoanalysis from Sigmund Freud. Unlike traditional linguistics, semanalysis addresses an element that is heterogeneous to language, the unconscious. The introduction of the unconscious into the science of signs, however, challenges the possibility of science, meaning, and reason. This is why Kristeva maintains that certain nineteenth-century poets whose work discharged unconscious drive force and emphasized the semiotic element of signification began a revolution in poetic language.

With semanalysis, Kristeva attempts to bring the speaking body, complete with drives, back into language. She does this both by putting language back into the body and by putting the body into language. She argues that the logic of signification is already present in the material body. In *Revolution in Poetic Language* she suggests that negation and identification—the two primary logical operations of language—are already operating within the body prior to the onset of signification: Expelling waste from the body prefigures negation and incorporating food into the body prefigures identification. The second way in which Kristeva brings the speaking body back to language is by maintaining that bodily drives make their way into language. One of Kristeva's major contributions to philosophy of language is her distinction between two heterogeneous elements in signification: the semiotic and the symbolic. Within Kristeva's writings, *semiotic* (*le sémiotique*) becomes a technical term that she distinguishes from *semiotics* (*la sémiotique*). The semiotic elements within the signifying process are the drives as they discharge within language. This drive discharge is associated with rhythm and tone. The semiotic has meaning but not does refer to anything. The symbolic, on the other hand, is the element of language that allows for referential meaning. The symbolic is associated with syntax or grammar and with the ability to take a position or make a judgment that syntax engenders.

Kristeva describes the relation between the semiotic and the symbolic as a dialectic oscillation. Without the symbolic there is only delirium, whereas without the semiotic, language would be completely empty, if not impossible. There would be no reason for people to speak if it were not for the semiotic drive force. The oscillation between the semiotic and the symbolic is both productive and necessary. The oscillation between rejection and stasis already existing within the material body produces the

oscillation between semiotic and symbolic in the speaking subject.

In *The Powers and Limits of Psychoanalysis*, Kristeva revisits the theme of revolution so prominent in her earlier work. In *Revolution in Poetic Language* Kristeva identifies the possibility of revolution in language—a revolution she deems *analogous* to social revolution—with (maternal) semiotic forces in avante-garde literature. In *Powers of Horror* this semiotic force of drives is not only associated with the maternal but more particularly with the abject or revolting aspects of the maternal. Here, the revolting becomes revolutionary through the return of the repressed (maternal) within (paternal) symbolic systems. Two decades later, in *The Sense and Non-Sense of Revolt*, Kristeva asks if revolt is possible today. In this book, volume one of *The Powers and Limits of Psychoanalysis*, she claims that within postindustrial and post-Communist democracies we are confronted with a new political and social economy governed by the spectacle within which it becomes increasingly difficult to think of the possibility of revolt. The two main reasons are that within media culture, the status of power and the status of the individual have changed. Kristeva argues that in contemporary culture there is a power vacuum that results in the inability to locate the agent or agency of power and authority or to assign responsibility. In a no-fault society, who or what can people revolt against?

In addition to the power vacuum, Kristeva identifies the impossibility of revolt with the changing status of the individual. The human being as a person with rights is becoming nothing more than an ensemble of organs that can be bought and sold or otherwise exchanged, what she calls the *patrimonial individual*. And, how can an ensemble of organs revolt? Not only is there no one or nothing to revolt against, but also there is no one to revolt. And without the possibility of revolt, especially the psychic revolt necessary for creativity, people are left with new maladies of the soul that make life seem meaningless.

In her *Female Genius* trilogy, Kristeva suggests that women with their attention to the sensory realm may provide an antidote for the meaninglessness that results from contemporary forms of nihilism. She argues that the genius of extraordinary women such as Hannah Arendt, Melanie Klein, and Colette help all women to see what is extraordinary in their own ordinary lives. Conversely, Kristeva maintains that the genius of everyday life is women's genius, particularly the genius of mothers; in creating new human beings, mothers are singular innovators, reinventing the child anew all the time. Kristeva

maintains that mothers may represent a safeguard against the automation of human beings.

## KROPOTKIN, PËTR ALEKSEEVICH

(1842–1921)

Pëtr Alekseevich Kropotkin, the geographer and libertarian philosopher, was the principal exponent of the theories of anarchist-communism. He was born of a line of Russian princes who claimed descent from Riurik, the reputed founder of the Russian Empire. His father was a general, and he himself seemed destined for a military career. He was educated in the Corps of Pages and served as personal attendant to Tsar Alexander II. When the time came for him to choose a career, Kropotkin applied for a commission in the Mounted Cossacks of the Amur and went to Siberia because he felt his chance of serving humanity was greater there than in Russia. He had already come under the influence of liberal ideas through reading the clandestinely distributed writings of Aleksandr Herzen.

In Siberia Kropotkin carried out an investigation of the Russian penal system, which aroused in him a revulsion against the effects of autocratic government. During the early 1860s he led a series of expeditions into the untraveled regions of Siberia and, on the basis of his observations, developed an original and influential theory concerning the structure of the mountains of Asia. He also made important discoveries regarding the glacial ages and the great desiccation of east Asia, which resulted in the onset of barbarian wanderings.

In the solitude of the Siberian wastes, Kropotkin's thoughts turned more and more toward social protest. In 1865 the exiled poet M. L. Mikhailov introduced him to the writings of the French anarchist Pierre-Joseph Proudhon, and in 1866 Kropotkin resigned his commission in protest against the execution of a group of Polish prisoners who had tried to escape.

For some years he devoted himself to science, and in 1871 he was exploring the eskers of Finland when he was offered the secretaryship of the Russian Geographical Society. It was the moment of decision. Kropotkin was already feeling the urge to "go to the people" that affected many of the conscience-stricken Russian noblemen of the

1870s, and he decided to abandon science. In 1872 he visited Switzerland to make contact with exiled Russian liberals and revolutionaries. After listening to many radical views, he went to the Jura, where the watchmakers were fervent disciples of Mikhail Bakunin. “When I came away from the mountains, after a week’s stay with the watchmakers, my views upon socialism were settled; I was an anarchist” (*Memoirs of a Revolutionist*).

In Russia Kropotkin joined the underground circle led by Nikolai Chaïkovskii. In 1874 he was arrested and imprisoned in the Peter and Paul Fortress. Two years later he made a sensational escape and returned to western Europe, where he became an active worker in the rising anarchist movement. In 1879 he founded *Le révolté*, the most important anarchist paper to appear since the end of Proudhon’s journalistic career in 1850, and in 1881 he took part in the London International Anarchist Congress, which founded the celebrated but short-lived “Black International.” In 1882 he was arrested by the French authorities and was tried at Lyons along with a number of French anarchists. He was sentenced to five years imprisonment for alleged membership in the International Workingmen’s Association. The sentence aroused wide international protest, and Kropotkin was released early in 1886. He went to England, where he lived until he returned to Russia after the 1917 revolution.

Kropotkin’s career in western Europe was sharply altered by his arrival in England. On the Continent, from 1876 to 1886, he had been a revolutionary agitator, conspiring, lecturing, pamphleteering, and taking part in radical demonstrations. His writings were mainly periodical pieces for *Le révolté*. At first they were topical, but by 1880 Kropotkin was already developing the theory of anarchist-communism in a series of articles later incorporated in two books—*Paroles d’un révolté* (Paris, 1885) and *La conquête du pain* (Paris, 1892).

### ANARCHIST-COMMUNISM

The doctrine of anarchist-communism differed from the collectivism preached by Bakunin and his followers in the 1860s in that it considered the need of the consumer rather than the achievement of the producer as the measure for distribution. In the vision of the anarchist-communist, the free-distribution warehouse would replace the earlier systems evolved by Proudhon and retained by the collectivists, which determined the worker’s due either by hours of labor or quantity of production. Also, the anarchist-communists laid particular stress on the commune (in the sense of locality), rather than the industrial association, as the unit of social

organization. In other respects—their rejection of the state, their stress on federalism, their emphasis on direct rather than parliamentary action, their denunciation of political forms—they did not differ profoundly from other schools of anarchism.

**SOURCES.** Although he became its leading exponent, Kropotkin did not originate anarchist-communism. The form of distribution embodied in the theory dates back at least as early as Thomas More’s *Utopia* (1515–1516), and it appeared in a modified form in François Marie Charles Fourier’s Phalansterian communities. The geographer Élisée Reclus, a former Phalansterian, appears to have brought the idea with him when he came to anarchism; it was first developed in writing by François Dumartheray, a Geneva artisan who helped Kropotkin in the founding of *Le révolté*. But Kropotkin developed the theory and, in *La conquête du pain*, he tried to show how it would work. This benign vision of an anarchist future reflects not only the optimism of Kropotkin’s views, but also the benevolence of his character. For, although he always paid homage to the ideas of violent revolution, he did so against his nature; as Lev Tolstoy shrewdly remarked, “His arguments in favour of violence do not seem to me the expression of his opinions, but only of his faith to the banner under which he has served all his life.”

### ANARCHISM AND SCIENCE

When he reached England, Kropotkin moved into a world where he was respected by people in all walks of life. His achievements as a geographer were remembered; he was honored by learned societies; his articles were published in scientific journals; and his books were welcomed by respectable publishers. He did not abandon his ideals, but his role changed from that of agitator to that of writer and libertarian philosopher.

The most important books Kropotkin wrote during this period were his autobiography, *Memoirs of a Revolutionist* (New York, 1899), and *Mutual Aid: A Factor of Evolution* (London, 1902). *Mutual Aid*, together with *Modern Science and Anarchism* (London, 1912), shows Kropotkin attempting to base anarchist theory on a scientific foundation. These books reveal him as a devoted evolutionist, to the extent that he explains revolutions as part of the natural process by which man, as a social animal, evolves. He sees revolutions arising obscurely in the consciousness of the people and punctuating the slow tenor of progress by sudden mutations in social organization, while he views anarchism as a backward trend toward a natural order that has been perverted by the emergence of

authoritarian institutions. Man is naturally social, he suggests; therefore he does not need government, which itself perpetuates the unequal conditions that breed crime and violence. In their sociality, human beings resemble the more successful species of animals that depend for their survival on cooperation among their members. This idea is the core of *Mutual Aid*, which is an attempt, based largely on the arguments of K. F. Kessler, to reform evolutionary theory by demonstrating that the neo-Darwinians wrongly stressed competition as a factor in evolution, to the exclusion of cooperation. In biological terms, his point was well taken; the appearance of *Mutual Aid* led to modifications in evolutionary theory. But Kropotkin never convincingly welded his ideal of mutual aid to his anarchistic love of freedom, since he ignored the extent to which customs restrict liberty in most societies in which nongovernmental cooperation dominates the pattern of life.

Kropotkin's departure to Russia in 1917 led to tragic disappointment. He found himself out of touch with Russian realities and isolated during the events that led to the October Revolution. He retired to the village of Dmitrov outside Moscow, where he spent his last years writing. He denounced the Bolshevik dictatorship and the terror it imposed. When he died in 1921, his funeral was the last great demonstration against communist rule.

## ETHICS

Kropotkin's last years were spent on the uncompleted *Etika (Ethics)*, which was published posthumously in Moscow in 1922. In part a history of ethical theories, this book seeks to present ethics as a science. In developing his naturalistic viewpoint, Kropotkin shows the emergence of morality among animals as an outgrowth of mutual aid and demonstrates its extension into human society, where it acquires a disinterestedness that goes beyond mere equality. He sees morality as the extension of human good will beyond equity and justice. The historical parts of *Ethics* are admirable, but the work is incomplete; Kropotkin's own ethical system is barely worked out.

## KRUEGER, FELIX

(1874–1948)

Felix Krueger, a German philosopher and psychologist, was born in Poznań and received his doctorate in 1897 from the University of Munich, where he studied under Hans Cornelius and Theodor Lipps. After working as an assistant at the Physiological Institute in Kiel he became a *Privatdozent* at Leipzig under Wilhelm Wundt. From 1906 to 1908 Krueger held a professorship at Buenos Aires, where he organized the development of scientific psychology in Argentina and left lasting traces of his views and activities. After returning to Leipzig he was called to Halle to succeed Hermann Ebbinghaus. In 1912–1913 Krueger was an exchange professor at Columbia University. In 1917, after three years of military service, he returned to Leipzig as Wundt's successor. At Leipzig Krueger founded the second Leipzig school of psychology, whose basic principles were designated as a genetic psychology of wholeness and structure (*genetische Ganzheits- und Strukturpsychologie*). In 1928 he received an honorary doctorate from Wittenberg College, Springfield, Ohio. In

1935 Krueger was appointed rector of Leipzig University. He immediately became involved in political conflicts and was removed from the rectorship and for some time forbidden to lecture; in 1935 he retired prematurely from academic life. Krueger edited two series of psychological works, "Neue psychologische Studien" and "Arbeiten zur Entwicklungspsychologie," from 1914 and 1926, respectively. Early in 1945 he moved to Switzerland.

Krueger's first work, a philosophical one, was *Der Begriff des absolut Wertvollen als Grundbegriff der Moralphilosophie* (The concept of the absolutely valuable as the basic concept of moral philosophy; Leipzig, 1898). In this work he presented a critique of Immanuel Kant running counter to that of Neo-Kantianism. He tried to show that there was a material vein in the formal ethics of Kant himself, and he stressed that ethical responsibility is moored in the person, in his "energy of evaluation" (*Energie des Wertens*) and in his attitude toward values (*Werthaltung*), which Krueger understood as the "core structure" of personality or character.

After this work Krueger turned to empirical and experimental psychology, in which he became known particularly for his new theory of consonance and dissonance based on the influence of the different tones and for experiments in phonetics and the psychology of speech. In connection with this work he began to develop, as early as 1900, a theory of psychological wholeness, arising from the exhibition of emotional and physiognomic experiencing, which he characterized as a quality of complexes (*Komplexqualität*) parallel to Christian von Ehrenfels's Gestalt qualities (*Gestaltqualität*). Together with his English friend and student (who was, nevertheless, older than he), Charles Spearman, Krueger introduced into psychology the calculus of correlation including the first reflections on factor analysis.

In 1915, in *Über Entwicklungspsychologie, ihre historische und sachliche Notwendigkeit* (On developmental psychology, its historical and factual necessity) Krueger developed a theory of cultural origins departing from Wundt's psychology of peoples and carried it further in *Zur Entwicklungspsychologie des Rechts* (The developmental psychology of law; "Arbeiten zur Entwicklungspsychologie," No. 7, Munich, 1926). In 1918 and (in English) in 1927, Krueger presented sketches for a theory of the emotions, which he defined as the *Komplexqualitäten* of one's total experience, that is, as supersummative qualities not to be confused or identified with gestalt.

These various strands, including his old moral philosophy, were united by Krueger in 1923 in a theory of structure, which was both critically related to and opposed

to the thought of Wilhelm Dilthey. Krueger defined structure as the new scientific conception of the mind, as "the organismic construct of psychophysical wholeness," that is, as the basis of events in experience in the form of disposition, attitude and readiness, inclination, habit, and capability. The existence and individuality of personal structure can be demonstrated particularly in experiences of personal significance and "depth," but also in the subjective predispositions or preconstellations of perception, thought, memory, etc. Structure is the bearer of development and of personal identity. Besides personal structure there are social and "objective" intellectual structures. Formally, the structure of the experienced gestalt, which exists in becoming, can be compared to the "actual genesis" (or microgenesis) of the gestalt. The development of man, like that of animals, arises from qualitatively complex, pregestalt experience and is only gradually differentiated into an articulated gestalt and into rational clarification. Krueger's last work, *Die Lehre von dem Ganzen* (The doctrine of the whole; Bern, 1948), began with psychology but culminated in cosmology.

There are four main points in Krueger's philosophical psychology: holism (opposition to associationism, emotionism (or emphasis on feeling and emotion), social evolutionism, and antiphenomenalism (structural personalism)). Krueger's genetic *Ganzheitspsychologie* was carried on by many of his outstanding students. Shortly after his death it was characterized as a "re-establishment of the science of the mind" in the full sense of the word, as opposing both mere introspectionism and mere behaviorism. It is the radical rejection of atomism, mechanism, sensationalism, and phenomenism (psychologism) of traditional psychology, whose loss of credit among academic psychologists is largely due to Krueger. The slogans and basic ideas of *Ganzheitspsychologie* have also stimulated and fertilized related fields, particularly aesthetics and education.

## KUHN, THOMAS

(1922–1996)

Educated at Harvard University (SB, 1943; PhD in physics, 1949), Thomas Kuhn taught at Harvard (1951–1956), University of California, Berkeley (1956–1964), Princeton University (1964–1979), and Massachusetts Institute of Technology (1979–1991). His book *The Structure of Scientific Revolutions*, first published in 1962 (2nd. ed., 1970), continues to stimulate discussion among historians and philosophers of science even as its concepts of “paradigm” and “paradigm shift” have been adopted by a great diversity of writers, often at some remove from their source in Kuhn’s book.

### CONCEPTUAL SCHEMES, PARADIGMS, AND NORMAL SCIENCE

At Harvard Kuhn became the protégé of its president, James B. Conant, to whom he dedicated the first edition of *Structure of Scientific Revolutions*. Conant’s concept of “conceptual scheme,” applied especially to the chemical revolution’s phlogiston and oxygen theories, reappeared in Kuhn’s first book, *The Copernican Revolution: Planetary Astronomy in the Development of Western Thought* (1957), and was one of the principal sources of Kuhn’s all-important paradigm concept. His evolving understanding of that concept also reflected a pivotal experience in 1947, in which he suddenly appreciated that

Aristotle could not properly be understood from the perspective of post-Galilean physics, but only from within Aristotle’s own context of problems, concepts, and assumptions. Kuhn’s early conviction that such systems of scientific thought can only be understood holistically and that a scientist’s appreciation for a radically new system comes in a flash of insight underlay his notions of the incommensurability of paradigms and of the gestalt switch that marks the transition from one paradigm to another.

Kuhn announced his central problem as “the nature of science and the reasons for its special success” (1970, p. v). He forged his concept of “paradigms”—glossed here as “universally recognized scientific achievements that for a time provide model problems and solutions to a community of practitioners” (p. viii)—in part as a way to understand why there is less disagreement among natural scientists over fundamentals than there is among social scientists and psychologists. Kuhn rejected the view that scientific knowledge grows incrementally through the accumulation of individual facts, laws, and theories. He linked his rejection of demarcationist issues—what distinguishes good science from error or superstition—to his insistence that superseded conceptual systems like Aristotelian dynamics and phlogistic chemistry were, in their context, no less scientific than currently accepted science.

Kuhn applied the term “normal science” to “research firmly based upon one or more past scientific achievements, achievements that some particular scientific community acknowledges for a time as supplying the foundation for its further practice” (1970, p. 10). Paradigm-defining works like Aristotle’s *Physics*, Isaac Newton’s *Principia*, and Antoine Lavoisier’s *Chemistry* were “sufficiently unprecedented to attract an enduring group of adherents away from competing modes of scientific activity” and “sufficiently open-ended to leave all sorts of problems for the redefined group of practitioners to resolve” (p. 10). Subsequent scientists (and students of science) study such works as “concrete models,” whereby they become “committed to the same rules and standards for scientific practice” (p. 11). Strong commitment and broad consensus characterize the practitioners of Kuhnian normal science. The paradigm that defines that practice limits the questions worth asking and the experiments worth performing as it specifies the entities the world is composed of and the relevance of putative facts.

For Kuhn, most scientists are engaged in “mopping-up operations” resembling “an attempt to force nature into the preformed and relatively inflexible box that the

paradigm supplies” (p. 24). Kuhn likened normal science to “puzzle-solving”: a solution must be assumed to exist for any problem worth addressing, and one knows ahead of time the general form the solution will take. Kuhn insisted that paradigms guide research not via rules and definitions but as models (later called “exemplars”) of proper scientific practice. He associated his understanding with Michael Polanyi’s concept of tacit knowledge and Ludwig Wittgenstein’s notion that one can employ words without having reduced their meaning to some putative essence.

In the context of his discussion of anomalies and the emergence of scientific discoveries, Kuhn began to employ the terms “paradigm” and “paradigm change” in a broader sense closer to his and Conant’s earlier “conceptual scheme,” whereby his central example was the chemical revolution associated with Lavoisier’s oxygen theory. Kuhn here insisted that unanticipated discoveries of new sorts of phenomena typically occur in response to the perception of anomaly with regard to the expectations of normal science. Kuhn likened scientists’ response to anomalies to subjects in an experiment with playing cards who are asked to identify—among normal cards—black hearts and red spades, and who typically try unconsciously to assimilate those anomalies to the expected categories: “In science, as in the playing card experiment, novelty emerges only with difficulty, manifested by resistance, against a background provided by expectation” (1970, p. 64).

### ANOMALIES, CRISES, AND PARADIGM SHIFTS

The point is of crucial importance. Anomalies enable scientists to isolate weaknesses within the dominant paradigm and to devise a solution that ultimately induces the scientific community to embrace a new and more effective paradigm. These are the “paradigm shifts” associated with the Copernican, Newtonian, and chemical revolutions. In Kuhn’s view awareness of serious anomaly—always with regard to internal, technical issues, not to any of various external factors—leads to a period of crisis characterized by “the proliferation of competing articulations, the willingness to try anything, the expression of explicit discontent, the recourse to philosophy and to debate over fundamentals” (1970, p. 91)—that is, by what he termed “extraordinary science.”

Although Kuhn recognized that “every problem that normal science sees as a puzzle can be seen, from another viewpoint, as a counterinstance and thus as a source of crisis” (p. 79), he offered no satisfactory explanation for

why only some unsolved problems are perceived as anomalies, and why only some anomalies lead to crises. In his view no fundamental changes to a paradigm can come from the resources of normal science itself. The transition from one paradigm to another constitutes “a reconstruction of the field from new fundamentals, a reconstruction that changes some of the field’s most elementary theoretical generalizations as well as many of its paradigm methods and applications” (p. 85). Kuhn likened such a paradigm shift to “a change in visual gestalt” (p. 84) and defined the associated “scientific revolutions” as “those non-cumulative developmental episodes in which an older paradigm is replaced in whole or in part by an incompatible new one” (p. 92).

### INCOMMENSURABILITY AND RELATIVISM

In elaborating parallels between scientific and political revolutions, Kuhn introduced a number of ideas that would prove controversial. He argued that because they recognize no common higher authority, “the parties to a revolutionary conflict must finally resort to the techniques of mass persuasion, often including force” (1970, p. 93).

Like the choice between competing political institutions, that between competing paradigms proves to be a choice between incompatible modes of community life. Because it has that character, the choice is not and cannot be determined merely by the evaluative procedures characteristic of normal science, for these depend in part upon a particular paradigm.... As in political revolutions, so in paradigm choice—there is no standard higher than the assent of the relevant community. (p. 94)

Such assertions led many to accuse Kuhn of making science a matter of might makes right, of mob psychology, where the techniques of political persuasion replace those of evidence and rational argument.

Because different paradigms make different ontological claims, define different problems as significant, and employ different standards of what properly belongs to science, “the normal-scientific tradition that emerges from a scientific revolution is not only incompatible but often actually incommensurable with that which has gone before” (1970, p. 103). Hence defenders of opposing paradigms, absent a shared set of values, “will inevitably talk through each other when debating the relative merits of their respective paradigms” (p. 109). Although Kuhn

resisted the charge of relativism, his position clearly relativizes scientific knowledge to the paradigm-dependent standards enforced by particular scientific communities, not to ostensibly objective experimental tests.

That implicit relativism was reinforced by Kuhn's insistence that scientists working within different paradigms see the world in profoundly different ways, that they effectively live in different worlds. Again, analogies—gestalt switches and experiments with inverting lenses and anomalous playing cards—were invoked to enhance the claim's plausibility. The transformation of vision that students undergo as they learn to read bubble-chamber photographs parallels “the shifts in scientific perception that accompany paradigm change” (1970, p. 117). The sudden and unstructured gestalt switch that accompanies a paradigm shift thrusts scientists into a world “incommensurable” with the one they had inhabited before. Kuhn's insistence that such transformations of vision are not reducible to a reinterpretation of individual stable data derived from his rejection of the possibility of a neutral observation language for science. In speaking of the “flashes of intuition through which a new paradigm is born” (p. 123), Kuhn transformed the gestalt switch from a metaphor to an operative element in the dynamics of scientific change. And in shifting the locus of conceptual change from the ostensibly objective externalities of experiment and argument to the psychological internality of a holistically unanalyzable gestalt switch, he seemed to many to undercut the epistemological legitimacy of science. Kuhn likened a revolutionary paradigm shift to a conversion experience that cannot be forced by logic and neutral experience. “Persuasion” and “conversion” are the terms that dominate Kuhn's discussion of paradigm shift.

Although he appealed to the greater problem-solving ability of postrevolution theories, Kuhn had no paradigm-independent way to define scientific progress and no way at all to address the question of the truth value of particular scientific claims. He sought to make this stance acceptable by appealing to an analogy between the historical development of science and Charles Darwin's rejection of the goal-directedness of evolution. The process by which one paradigm wins out over its competitors “is the selection by conflict within the scientific community of the fittest way to practice future science. ... Successive stages in that developmental process are marked by an increase in articulation and specialization. And the entire process may have occurred, as we now suppose biological evolution did, without benefit of a set goal, a permanent fixed scientific truth, of which each

stage in the development of scientific knowledge is a better exemplar” (1970, pp. 172–173). But goal-directedness is not the same thing as correspondence to the physical world, and although this may be a viable way to account for the history of science, it does not address the underlying epistemological question concerning the truth-likeness of scientific theories. In asking why scientific communities are able to reach consensus at all, Kuhn failed to assign a principal role to inputs from the physical world as he increasingly appealed to the sociology of scientific communities.

## SCIENTIFIC AND LINGUISTIC COMMUNITIES

In the postscript appended to the second edition of *Structure of Scientific Revolutions*, Kuhn defended his original claims while effectively abandoning the term “paradigm.” One important amplification was his appeal to the analogy between members of scientific and linguistic communities, whereby he urged “that men who hold incommensurable viewpoints be thought of as members of different language communities and that their communication problems be analyzed as problems of translation” (1970, p. 175). Like the acceptance of a new paradigm, Kuhn saw the transition accompanying translation into a new language as a qualitatively discontinuous conversion experience: “The conversion experience that I have likened to a gestalt switch remains, therefore, at the heart of the revolutionary process” (p. 204).

## KÜLPE, OSWALD

(1862–1915)

A German psychologist, philosopher, and historian of philosophy, Oswald Külpe was born in Kandava, Latvia. After teaching history, Külpe entered the University of Leipzig in 1881, intending to continue in history. However, the lectures of Wilhelm Wundt stimulated his interest in philosophy and psychology, and after further studies in Berlin, Göttingen, and Dorpat (Russia), he returned to Wundt's seminar in 1886, receiving his doctorate the following year. In 1894 he was appointed extraordinary professor at Leipzig but left to accept a full professorship at Würzburg, where he founded a psychological laboratory. Külpe returned to Leipzig in 1896, and he subsequently held academic positions at Bonn and Munich. Primarily because of his work in organizing experimental laboratories, Külpe is regarded as a pioneer of experimental psychology in Germany. He died in Munich during World War I of influenza contracted while visiting wounded German soldiers.

## PSYCHOLOGY AND EPISTEMOLOGY

Külpe's philosophical position, a form of critical realism, was closely related to his work in psychology. He came to regard the positivistic attempts of Ernst Mach and Richard Avenarius to reduce mental processes to sensa-

tions as incapable of accounting for the findings of introspective experiments. In one series of experiments, Külpe presented cards with nonsense syllables of varying colors and arrangements to subjects who were asked to report either the color, pattern, or number of items seen. Each person abstracted the features he had been instructed to report, remaining unconscious of the other features of the cards. Külpe concluded that the process of abstraction depends not only on the material presented to sensation but also on the subject's apprehension. This was taken to prove that sensations—as well as physical phenomena—must be distinguished from their apprehension. Thus he questioned the equation of "being" with "being perceived," even at the level of sensation.

Külpe abandoned the sensationalist psychology of contents in favor of a psychology recognizing both contents and acts of mind. Abstraction, he maintained, is a mental act or function that cannot be directly observed, but its occurrence is undeniable, even though it is discoverable only retrospectively. There exist both thought contents (*Gedanken*) and thought processes (*Denken*). The latter include the impalpable acts of thinking, meaning, and judging, which are not merely relations among contents but activities of the ego that transform the actualities (*Wirklichkeiten*) of consciousness into realities (*Realitäten*).

Külpe's position was thus hostile to both naive realism and idealism. Against the former, he argued that thought, although it does not produce the object of knowledge, is nevertheless genuinely spontaneous and creative in contributing to the realization of the object. His argument against idealism held that the facts of conscious experience require the existence of independent objects. When a scientist studies the maturation of an egg, for example, he assumes that this process takes place while no consciousness is directed upon it. Such continuity of development implies the object's independence of its being thought, a presupposition of every science.

Külpe used the word *awareness* (*Bewusstheit*) to indicate that the meanings of abstract words can be discovered in consciousness even when only the words themselves are perceivable entities. This thesis is an application of the theory that there exist impalpable (*unanschaulich*) or imageless contents of consciousness, a theory for which Külpe's "Würzburg school" of psychology was noted. Meanings can be experienced and objectified even without words or other signs. Although we cannot analyze precisely how these contents are given, retrospective acts make the world of meanings accessible to us. Külpe's indebtedness to Edmund Husserl and Franz

Brentano is evident. Mental acts provide knowledge of meanings, and the act of meaning (*das Meinen*) may be directed even to such objects as God, the soul, electrons, or atoms, which could not possibly be actualized in consciousness. The capacity for imageless thought is essential if thought is to relate itself to something independent of it. When one wants to imagine a certain structure, the particular image one has in mind is only representative of the structure; the image points beyond itself or is the occasion for such an intentional act.

## AESTHETICS

In aesthetics, Külpe attempted to support Gustav Fechner's results concerning the golden section. Like Wundt, he maintained that the aesthetic pleasure produced by ideally proportioned objects results from mental economy. When the ratio of a whole to its larger part is the same as that of the larger to the smaller part, the perception involves the least effort combined with the greatest possible diversity.

Külpe attempted to further the development of experimental aesthetics by such methods as asking people to record their reactions to glimpses of slides showing works of art. His findings indicated no sympathetic empathy on the part of his subjects, thus opposing the contention of Theodor Lipps that such empathy (*Einfühlung*) is the basic condition of all aesthetic enjoyment. In the reports of his subjects Külpe found that form, orderliness, symmetry, and harmony were related to attractiveness. However, he recognized the limited validity of his findings, admitting that aesthetically inexperienced people might respond differently than his subjects. This reluctance to claim more for a theory than was warranted by experimental findings was characteristic of Külpe's work in psychology.

## KUMAZAWA BANZAN

(1619–1691)

Kumazawa Banzan, a Japanese Confucianist of the Wang Yangming school, was born in Kyoto and died at Koga, Shimoda prefecture. Both he and his father were masterless samurai. Deciding to become a scholar, Kumazawa went to Nakae Tōju (1608–1648); in 1642 Nakae taught him the doctrine of Wang Yangming (in Japanese, Ōyōmei)—“innate knowledge” and cultivation of the mind. Kumazawa entered the service of Lord Ikeda Mitsumasa of Okayama, but his ideas, contrasting with the officially established doctrine, Zhu Xi neo-Confucianism, aroused suspicion. However, his character and practical ability were recognized, and Ikeda put him in charge of the fief. For seven years (1649–1656) he successfully brought forth administrative reforms that transformed Okayama into a model fief. Paramount among his accomplishments was his role in organizing the Okayama college. Yet the extreme nature of these reforms, even in monasteries, angered many. Moreover, there were rebellious samurai among his pupils. He decided to retire to the studious life of a teacher in Kyoto, but slander of his teaching forced him to move in 1667; he did pass eight quiet years (1679–1687) at Yadasan near Kōriyama. On the official request of the Tokugawa government, he presented a plan of reform (possibly in his *Daigaku wakumon*). Thereupon his enemies, especially Hayashi, the defender of Zhu Xi Confucianism, succeeded in having him confined at Koga.

Kumazawa is typical of the early Tokugawa nonconformists, who were beset by adversities that multiplied with success. His politico-economic ideas, which were indeed very bold for his times, were the real reason for his

difficulties. They are expressed in *Daigaku wakumon* (Some questions concerning the great learning), which is not a commentary on the Confucian classic “The Great Learning” but rather a tract on many subjects concerning how to rule the realm according to the Confucian precept of *jinsei*, or “benevolent rule.” Both his unconventional proposals and his pragmatic attitude toward doctrine are striking.

## LAAS, ERNST (1837–1885)

Ernst Laas, the German philosopher, was born in Förstentalde. From 1872 on, he was professor in Strasbourg. His first important book, *Kants Analogien der Erfahrung* (Berlin, 1876), was a critical study both of Immanuel Kant and of “the foundations of theoretical philosophy”; but in his main work, *Idealismus und Positivismus* (3 vols., Berlin, 1879–1884), he launched a general attack on idealism, including Aristotle, René Descartes, Gottfried Wilhelm Leibniz, and especially Plato as its founder, as well as Kant. His purpose was to provide a remedy for the “discontinuity of philosophy”; that is, its failure to make progress over the centuries and its want of any clear standards. The remedy lay first of all in a new critical approach to the history of philosophy, which in the past had usually been at best merely scholarly and accurate. This new analysis revealed a basic dualism throughout the history of philosophy between the outlooks of Plato and Protagoras; and this revelation, in turn, permitted a revision of the judgment rendered in favor of Plato that had ever since benefited his followers at the expense of their opponents, such as the British empiricists. Laas referred specifically to J. S. Mill and cited approvingly a

review of his own book on Kant that had compared it to Mill’s *Examination of Sir William Hamilton’s Philosophy*.

By “positivism” Laas meant, as was usual in Germany at the time, the tradition of Protagoras and the British empiricists, not the doctrine of Auguste Comte, whom Laas mentioned rarely and with little sympathy. Laas’s position might more accurately, especially in English usage, be called neo-empiricism. It proposed to limit knowledge to the data of sense experience, thereby denying both a consciousness independent of the content of perception (insisting on the correlation of subject and object) and objects independent of the process of perception (asserting the instant changeability of objects of perception). At the same time Laas avoided the conclusions drawn by some empiricists, such as George Berkeley, by rejecting any version of subjective idealism (which would assert the superiority or exclusive reality of the perceiver vis-à-vis the objects of perception or sensation) even more vehemently than he rejected the objective idealism originated by Plato. He identified this idealistic tradition in logic with conceptual realism, in epistemology with a priori deductive rationalism, and in metaphysics with both spontaneous human creativity and superhuman teleology. He associated idealism with a mathematically

inspired desire to attain to the knowledge of absolutes and with the doctrines of innate ideas and final causes.

However, in his anxiety to escape from the “monstrous” notions of subjective idealism, as well as from “skepticism,” “frivolity,” and the “banal philosophy of common sense,” Laas came close to a neo-Kantian position in postulating an ideal or total consciousness. Recognizing, with Mill, that the sum total of actual objects of sensation is insufficient to construct an intelligible world, he asserted that the world consists of the sum total of possible contents of perception, which would be vouchsafed to an ideal consciousness and which it is the task of philosophy to construct. Since facts (objects) exist independently of consciousness (although not of perception), including this ideal consciousness, Laas claimed in this way to have saved the possibility of scientific investigation of the physical world from “skepticism,” even though that world is relative and variable.

Just as he quite openly sided even with idealism (particularly with Kant, whom he often cited sympathetically) rather than with epistemological skepticism, Laas also seeks to defend his ethical doctrine (mainly in Vol. II of *Idealismus und Positivismus*) against any imputation of relying on egoism. Here again, however, his main concern was to overcome what he saw as the Platonic tradition of asceticism founded on a set of absolute and transcendental ideals. For this he proposed to substitute a “positive” ethics for this world, based on its values as revealed by “enlightened self-interest.” Laas acknowledged the founders of this ethical doctrine to be Epicurus, Claude-Adrien Helvétius, and Jeremy Bentham, but he diverged from them on the crucial point of egoism. He denied the identification of self-interest with egoism and held, rather, that self-interest dictates the performance of duties and the fulfillment of demands and expectations imposed on the individual by his environment. In this way, ethical values are the consequences of a particular social order. They acquire validity when they are judged, in the long run and by a considerable number of people, to be worthwhile. Laas characteristically listed as ethically desirable values security of employment, social harmony, the laws and institutions of the state, and cultural progress. These ethical teachings were the most influential part of his philosophy, affecting, in particular, the ideas of Theobald Ziegler and Friedrich Jodl.

## LABERTHONNIÈRE, LUCIEN (1860–1932)

Lucien Laberthonnière, the French philosopher of religion and a leading figure in the modernist movement in the Roman Catholic Church, was born at Chazelet (Indre). He studied for the priesthood and was ordained as an Oratorian in 1886. He then taught in various institutions, mainly in the college at Juilly, where he became rector in 1900. Laberthonnière was influenced by philosophies of life and action; he mentions Maine de Biran and Étienne Boutroux as the two philosophers who had most impressed him. Maurice Blondel's philosophy of action was another important formative factor, although Laberthonnière later found it moving too far toward intellectualism. He himself not only advocated a pragmatic point of view but also had an intense distaste for intellectualism and speculative philosophy. In particular, he had no sympathy for the attempted Thomist synthesis of faith and reason, believing that the task is not to conciliate these two but to choose between them. His teachings brought him into conflict with ecclesiastical authorities, and his principal writings were put on the Index in 1906. In 1913 he was prohibited from further publication.

Laberthonnière was not concerned with merely speculative philosophy that is constructed apart from life. He believed that the purpose of all philosophy is to give sense to life, and this motivation underlies even metaphysics, whether or not the metaphysician is aware of it. In the long run, the test of a philosophy must be its viability or its aptness for life, and the criterion of philosophical truth is a pragmatic one. We mistake the character of philosophy if we think of it as a theoretical enterprise resulting in a system of propositions linked together by abstract

logical principles. A philosophical doctrine has a moral as well as an intellectual character, so that a worthwhile philosophy has to be worked out by living. The test of its truth is whether it can be illuminating when brought to bear on the problems of life.

Although Laberthonnière apparently held that all philosophy has a pragmatic or existential motivation, even if this remains unconscious, he also believed that some philosophies have been much more successful than others in relating to life. The theme of one of his principal writings, *Le réalisme chrétien et l'idéalisme grec* (Paris, 1904), is the contrast between two supposedly extreme cases, Greek philosophy and Christian thought. Greek philosophy was concerned with abstract essences, conceived God as static and immutable, and proposed the life of pure contemplation as its ideal for man. In contrast to such idealism or intellectualism, Christianity is presented as a realism. Its concern is with the concrete life of action, and God himself is conceived as active, the living God of the Bible. Hence, the truth of Christianity cannot be reached by intellectual contemplation, as if it were something external to us. Such truth as Christianity teaches is concrete and intrinsic to life, so that we grasp it only in living and in re-creating this truth in ourselves. These ideas about religious truth had already found expression in Laberthonnière's *Essais de philosophie religieuse* (Paris, 1903), where it is maintained that the doctrines of religion are to be understood not as general truths of the same kind as scientific truths but as concrete truths that must be brought into experience and realized if we are to understand them and know their value.

Although these views lean strongly toward pragmatism, Laberthonnière did not think that religion could be reduced to a purely practical affair or that it could be adequately explicated in naturalistic terms. It is significant that in spite of the harsh treatment that he received from the Roman Catholic Church, he remained devoted to it and believed his philosophical views to be compatible with its teaching. If he went far toward abolishing the traditional distinction between the natural and the supernatural, this is not to be understood as the reduction of the latter to the former. Rather, it was Laberthonnière's conviction that the natural is itself already permeated by divine grace. Thus, we should look for God not in some upper or outer realm but in the immediate world, where he is active, and especially in the depth of human life itself.

## LABRIOLA, ANTONIO (1843–1904)

Antonio Labriola, professor of philosophy in Rome from 1874 to 1904, was the first Italian Marxist philosopher. He wrote little, but that little was widely publicized by two disciples, Georges Sorel and Benedetto Croce; he exercised his extensive influence through lectures and discussions. Trained as a Hegelian in Naples, he became a Herbartian, more interested in Johan Friedrich Herbart's ethics and pedagogy than in his metaphysics. He discovered Marxism around 1890 and began a correspondence with Friedrich Engels that lasted until the latter's death and was published in *Lettere a Engels* (Rome, 1949). This discovery of Marxism was a decisive event in Italian intellectual life, for from it dates the introduction of Marxist theory into Italy's academic culture, where it still occupies a prominent place.

Labriola's articles on Marxism, published in Italy by Croce and in France by Sorel, were first collected in French, as *Essais sur la conception matérialiste de l'histoire* (Paris, 1897). Their publication established Labriola's international reputation as an expositor of Marxism. He wrote Sorel ten letters on the subject, published as *Discorrendo di socialismo e di filosofia* (Rome, 1897). These books were the first exposition of Marxism as an independent philosophy to be made by an academic philosopher. They have been widely used in later efforts to combat all varieties of philosophical revisionism, whether from neo-Kantian or positivist sources. The "return to Labriola," as recommended by Antonio Gramsci and as undertaken in Italy since 1950, has meant going back to the original innocence of a supposedly pure and independent Marxist philosophy, for Labriola claimed not to be an original thinker, and even less to be interested in developing or criticizing Marxism. He wanted to be simply an expositor and systematizer of a philosophy implicit in Karl Marx's work.

The philosophy he found in Marx's work closely resembled the Hegelian views that Labriola had defended in controversies with neo-Kantians before he had heard

of Marx. For example, he held that scientific socialism is not subjective criticism applied to things, but the statement of the self-criticism that is in things themselves. The only criticism of society is society itself, for there is an objective dialectic immanent in history, which progresses by contradictions. Socialism was no longer an aspiration or project (a view soon to be revived by neo-Kantian revisionists); it was the inevitable result of current contradictions in capitalist society. Labriola stressed the “scientific, objective” status of these assertions, in contrast to mere philosophies of history, which he dismissed as ideology. Historical materialism was no philosophy, but simply a method of research, a guiding thread like the Darwinian hypothesis.

Labriola, Croce, and Sorel were nicknamed the Holy Trinity of Latin Marxism, but the Roman professor came to feel that his spiritual sons were “going too far” in their development and criticism of the doctrine. They lacked that inflexible orthodoxy of which Labriola is the first eminent example in the Marxist tradition, and they touched off the revisionist controversy. That dispute broke out simultaneously in several countries, although Croce gave priority to his own and Sorel’s writings. At all events, Eduard Bernstein in Germany, Sorel in France, Croce and Saverio Merlino in Italy, T. G. Masaryk in Prague, and the Fabians in England drew freely on each other’s work, and Labriola found himself being quoted by and confounded with the “heretics.” In a celebrated dispute, he broke publicly with Croce and Sorel, saying that revisionism was an international conspiracy organized by “scientific police-spies”—perhaps the first appearance of a philosophical terminology that was to become familiar later. Labriola never wrote on Marxism again. His earlier minor works, which include a *Socrate*, have been published by Croce (Bari, 1909) but are of small importance.

## LA BRUYÈRE, JEAN DE

(1645–1696)

Jean de La Bruyère, the French author and moralist, was born in Paris, the son of a city official. After some legal training he apparently fell on hard times, but through the influence of Jacques Bénigne Bossuet he was appointed tutor to the grandson of the great Condé in 1684. After his tutorial functions were ended, he stayed on as librarian. The family seems to have been unpleasant; his colleagues, uncongenial; and the humiliations inflicted on him in this aristocratic society left a lasting mark. Elected to the Academy in 1693 after several unsuccessful attempts, he led a lonely and somewhat frustrated life, never marrying, making few friends, but showing passionate loyalty to those who, like Bossuet, won his respect.

La Bruyère’s one famous work, the *Caractères*, reflects his personal experiences. Ostensibly modeled on the Greek *Characters* of Theophrastus, which La Bruyère translated and published in the same volume, the *Caractères* owes more to the quite different genre of La Rochefoucauld’s *Maximes* and to the work of such contemporary moralists as Blaise Pascal and the Chevalier Antoine Gombault de Méré. Fifteen chapters somewhat arbitrarily group together epigrams (although La Bruyère explicitly disclaimed any intention of producing anything so authoritative as maxims), extended pen portraits (readily, and often wrongly, identified with living people) and brief moral essays, all arranged to cover, with considerable overlapping, the main characteristics and activities of contemporary society, from literary criticism to money lending, from sex to sermons. The last chapter, which, La Bruyère implausibly claimed, constituted the purpose

and culmination of the previous fifteen, is devoted to a defense of religion against the freethinkers. It combines in an agreeable rather than a compelling manner the stock arguments for God's existence from his visible effects in nature with others reminiscent of Pascal and drawn from human psychology. The length of the book more than doubled in the course of nine editions from 1688 to 1696, and it came to include more and more of the concrete and detailed description, based on acute observation and couched in brilliant style, which makes La Bruyère at once a distinctive and a distinguished author.

In La Bruyère's time the splendors of Louis XIV's reign had come to demand too high a price, both economically and morally, of those obliged to maintain it. La Bruyère, a bourgeois himself, soured by personal experience of aristocratic arrogance and temperamentally allergic to worldly frivolity, was unsparing in his criticism of the court, where methodical hypocrisy marked the lives of those enslaved by self-interest and the desire for royal favor.

Like Bossuet, his hero and patron, La Bruyère felt able to combine vehement attacks on social abuses, due certainly in fact (if not in theory) to royal absolutism as currently practiced, with fulsome eulogy of Louis himself, going so far as to assimilate respect for the prince to fear of God. A convinced Christian, he had a genuine social conscience, as is illustrated by his famous remarks about the pitiful condition of the peasants. He contrasted the elegant heartlessness of the nobles with the rough kindness of the people, with whom, in the last analysis, he would wish to be classed. He was, however, neither egalitarian nor republican, but believed that inequality founded on order is divinely instituted; and it was on moral and religious grounds, not in the name of equality, that he dissociated himself from a society he regarded as irremediably corrupt.

In common with other moralists of the age, La Bruyère was fascinated by the discrepancy between appearance and reality in human behavior. He recorded how skill in playing the social game usurps the name and place of virtue, how fashion makes mock of convictions (a happily married couple finds it socially expedient to simulate infidelity), and how self-interest is the one constant motive of those who disguise it so ingeniously. He was, however, gloomy rather than hopeless about human nature, and did not despair of the potential goodness of men as yet uncontaminated by society. He also believed in the possibility of satisfactory human relationships, speaking with attractive warmth of love and friendship.

Moderate as well as modest, La Bruyère was saved by common sense from the clever cynicism that is purely destructive, and his work is characterized by a positive and humane quality underlying the bitterest criticism. Although the *Caractères* falls short of absolute greatness, it reflects with exceptional accuracy the wane of the *grand siècle*.

## LACAN, JACQUES

(1901–1981)

Jacques Lacan is undoubtedly the most philosophical of psychoanalytic authors. He developed his psychoanalytic theory of subjectivity—as a ferocious critique of the modern metaphysical tradition—in direct dialogue with a number of major philosophical figures: Descartes, Kant, Heidegger, and many others.

Lacan never had any formal philosophical training. After studying medicine and psychiatry, he got involved in the surrealist movement in the early 1930s. Along with Sartre and Bataille, he participated in Alexandre Kojève's famous seminars on Hegel's *Phenomenology of Spirit* at the Ecole des Hautes Etudes en Sciences Sociales. Lacan joined the Société Psychanalytique de Paris in 1936. Both his theories—specifically his critique of ego psychology, which he carried out under the label of a “return to Freud”—and his practice of short psychoanalytic sessions caused discord within the French and the international psychoanalytic movement in the fifties. As a result of this rift, Lacan and his followers founded the Société française de psychanalyse in 1956 and later the Ecole freudienne in

1963. In the beginning of the fifties, Lacan also started to give seminars in Paris that not only attracted psychoanalysts but also a great number of philosophers such as Jean Hyppolite and Paul Ricoeur. In this way, psychoanalysis became a central force within French philosophical thinking of the second half of the twentieth century.

Lacan's theory of the mirror stage is his first original contribution to psychoanalytic thinking. This theory was first formulated at a conference in Marienbad in 1936. Although it is a reformulation of Freud's theory of narcissism, it has important consequences for the philosophical reflection on the status of the subject. Indeed, according to Lacan, the ego is an effect of an identification with an image (paradigmatically the mirror image) that represents an ideal of unity and completeness and that is not the ego itself: "*Je est un autre.*" The ego is thus characterised by an alienation that cannot be undone. It gains access to itself only through the image of the other. In the mirror stage—and in all "imaginary" relations that function according to the same logic—the ego misrecognizes its difference from the image/ideal with which it identifies itself and of which it believes that it expresses its very essence.

Lacan's work of the 1930s and 1940s mainly consists of a detailed exploration of the characteristics and the dynamics of the mirror stage and the realm of the imaginary that is characterized by it. In this context, he specifically focuses on typical forms of human aggression. Human aggression is not primarily an effect of the frustration of vital needs. Indeed, since the ego structurally misrecognizes its difference from the image/ideal of the other with which it identifies itself, the latter also inevitably appears as an usurper that provokes aggressiveness. S/he indeed appears in the process at a place that seems to be rightfully mine. I desire what s/he desires because, on the basis of the identification, I am what s/he is. As a consequence, this desire is intrinsically conflictual. Lacan often refers in this context to Saint Augustine, who describes a scene in which a well-fed infant expresses uncontrollable anger at the sight of his baby brother being breastfed. This is a clear illustration of one of the meanings of Lacan's famous dictum that "desire is the desire of the other."

This intrinsic link between the mirror stage and human aggression explains why Lacan thinks of the former as an impasse that has to be overcome. The emergence of structuralism in the early fifties, and more particularly the publication of Levi-Strauss's *The Elementary Structures of Kinship* in 1949, allowed Lacan to explain once and for all how overcoming this impasse is

possible. He now claimed that the symbolic order—the order of language and of the law—precedes and dominates the imaginary that is structured by it. Hence, the identification with the mirror image is only possible on the basis of a symbolic point of reference: "Look, that image in the mirror, that is little Jimmy."

Whereas in the thirties and forties Lacan mainly studied the dynamics of imaginary relations, during the fifties he focused on the relation between human beings and the symbolic order that he calls "the Other." Lacan turns to Hegel's idea that "the word is the murder of the thing." Entry into the symbolic order implies a loss of immediacy that desire tries to undo. This desire is essentially dependent on the symbolic order through which it takes shape. Humans desire in accordance with the symbolic systems in which they are born. Lacan shows, for instance, how the inability to write of one of his patients was linked to his youth in a Muslim country. When he was small, his father was accused of theft and, according to Islamic law, the hands of a thief should be cut off. This illustrates the second meaning of Lacan's dictum, "Desire is the desire of the Other." Here "the Other" indeed refers to the symbolic system—in the case of Lacan's patient: Islamic law—in which the subject participates without realizing its impact.

In the early 1960s, Lacan shifted his attention from the imaginary and the symbolic to the Real and the object a. Language consists, according to Lacan, of differentially determined signifiers whose meaning is completely dependent on the context in which they are used. Because there is no ultimate context that would end the production of meaning once and for all, the loss of immediacy can never be overcome or "sublated" in an ultimate synthesis. Something is irremediably lost and cannot be recuperated into the order of meaning (the imaginary and the symbolic). This is what Lacan calls the Real. This notion is intrinsically linked to Lacan's theory of the object a that is the cause (and not the telos) of desire. Examples of objects a include Freudian part-objects such as breast and feces as well as the voice and the gaze, which are paradigmatic examples of the object a, according to Lacan. The object a is a (dis)incarnation of the lack that causes desire: it gives the lack a bodily determination, on the one hand; at the same time, however, these objects cannot be grasped in the phenomenal world (when we reach for the gaze, we touch ... the eye). In this way, they refer to the infinite character of human desire.

From the early 1960s onward, Lacan became more and more interested in topological figures like Borromean knots or rings. He believed that they could be used

to articulate the fundamental structures of human subjectivity. Lacan died in 1981 in Paris.

## LACHELIER, JULES (1832–1918)

Jules Lachelier, the French idealist, was born at Fontainebleau and studied at the École Normale Supérieure in Paris. He received his *docteur ès lettres* in 1871 and held various professorial and administrative positions in the French educational system until his retirement from the post of *inspecteur général* in 1900. Lachelier joined with his teacher Jean Gaspard Félix Ravaisson-Mollien in founding the neospiritualist movement in French philosophy, a movement opposed to what seemed to be the naive acceptance of science and the scientific attitude in all phases of life. Among those who have acknowledged Lachelier's influence are Émile Boutroux, Victor Brochard, Jules Lagneau, and Henri Bergson.

Lachelier advanced a number of skeptical arguments that tend to reduce objects to phenomena, phenomena to sensations, and, more generally, to resolve the external world into thought. Nevertheless, he retained the conviction that we live in a common, objective world. Accord-

ingly, his philosophy is directed toward the conclusion that the objectivity of our knowledge and experience is derived from mind. He summarized his idealistic philosophy as the discovery of "a thought which does not think, suspended from a thought which thinks itself"

To avoid the pitfalls of both the empiricism and the spiritualism of his day, Lachelier attempted to provide a basis for induction in a philosophy of nature. His procedure consisted of a Kantian reflection upon the necessary conditions for the existence of the world as we know it. He began by observing that, if knowledge is to be possible, sensations must exhibit the same unities that are found in phenomena. By eliminating competing hypotheses, he found that the unifying element within any phenomenon, as well as the unifying element among phenomena, is established by the necessary relations operative in them and is expressed by the law of efficient causes. The necessity of this law cannot be discovered in sensations alone, in phenomena as such, or in their mere juxtaposition; nor can it be isolated in any locus from which mind is separated. It must be regarded, rather, as a kind of unconscious but logical thought diffused throughout nature. The mechanical linkages among events in nature reflect the logical relations in thought. Lachelier concluded that the unity of thought and the formal unity of nature are inverses of each other.

Given a series of phenomena, the law of efficient cause is sufficient to account for their organization in a mechanically interrelated series. But the questions remain: Why do whole phenomena occur? How are several series of mechanically ordered individual phenomenal objects coordinated into groups in order to form complex and recurrent phenomena? The question of recurrence involves the problem of induction and indicates that some principle—in addition to the law of efficient causes—must be found to explain the recurrence of phenomena. If we are neither to stretch the principle of efficient causes beyond reasonable bounds nor to supplement it with some occult principle *ex machina*, then we must suppose that the whole phenomenon—complex yet persistent—contains the reasons for its unity and recurrence. Lachelier, like Immanuel Kant, recognized a whole to be an end when the whole contained the reason for the organization of its parts. (A whole of this kind is illustrated in a stable chemical compound or in a living organism.)

Thus, in view of the fact that we indisputably are aware of phenomena which are harmonious and recurring complexes or wholes of this sort, Lachelier arrived at a second principle: The law of final causes. By its opera-

tion, *sensa* are grouped into perceptions of which we are actually aware, and thus they provide content and reality for the necessary but empty form of the universal mechanism. This law is to the matter of phenomena what the law of efficient causes is to their form. In these terms the distinction is drawn between the abstract existence of mechanical nature and the concrete existence of teleologically unified but contingent individuals. Since all actual objects are complex, they all presuppose the operation of the law of final causes. This law is, then, prior to the law of efficient causes in respect to actual existence.

These two laws are not on the same logical footing. Lachelier regards the law of efficient causes as proved. The proof is of the Kantian type. Given coherent experiences, this law, which is logic projected into phenomena, expresses the condition under which they cohere and are intelligible. The law of final causes, however, is not reached in the same way. Presumably, simple phenomena might remain logically ordered while being grouped in different ways. Their actual grouping into the harmonious and persistent unities that we experience is the consequence of a law which operates more like an act of will than like a formal or logical requirement. Thus, the law of final causes is said to be regulative only.

The twin laws of efficient and final causes provide the foundation for induction. Induction is thereby “founded” in the sense that it is partly proved or derived from the conditions for experience and partly justified as expressing a teleology of nature. The practice of induction, therefore, may be expected to be partly the logical deduction of events from previous events, and partly a “divining” that natural phenomena will cooperate with each other in a given way under given circumstances.

This foundation, however, is not ultimate. It does not explain why these two laws alone are the ordering principles of our existent world. Lachelier, in considering this point, observed that some organisms realize to a higher degree than others that harmony toward which nature moves. In fact, the law of final causes entails a whole hierarchy of beings that increase in order and harmony. The more complexly unified organisms in nature are not the chance products of accidentally unified simpler organisms. Rather, the simpler organisms, implicit in the more complex ones, are separated from them by a kind of “division and refraction.”

The human being can free himself in thought from the particular mechanical conditions of phenomena. He has the capacity to separate some perceptions from others and, using them as symbols, to represent general properties of things. In his ability to abstract and gener-

alize, the human being, although distinguished from all other things by this capacity, can be said to be in contact with the whole universe. The universe can be discovered again in thought but under a new condition, freedom. In addition, man is free because he can select the means and ends of his activity by reference to ideas. Hence, through man, the realm of final causes and the freedom that is its condition penetrate the organic and mechanical realms. Furthermore, without freedom it would be impossible to conceive of either mechanism or finality. Thus, the laws of efficient and final causality, upon which induction is founded, are themselves founded upon freedom—and freedom is the essential property of thought.

The process of founding induction within a philosophy of nature, therefore, consists partly in a demonstration and partly in a discovery of regulative rules. Finally, the process terminates in a metaphysics that affirms the basic reality of thought. This metaphysics is intended to found the philosophy of nature in the sense of providing a reason for belief in the unity of its laws and in its idealistic source. Lachelier’s metaphysics of freedom is further developed in his article “Psychologie et métaphysique” (1885) and is given a religious dimension in “Le pari de Pascal” (1901).

## LAKATOS, IMRE

(1922–1974)

### LIFE

Imre Lakatos did important work in the 1960s and 1970s in the philosophy both of mathematics and science. He was born Imré Lipsitz in Debrecen Hungary, and by the time he left for England after the Hungarian Uprising in 1956, he had already lived a complex, charged, and controversial life. A convinced and influential Marxist, he had been unofficial leader of a group of young Jews in hiding from the Nazis after the invasion in 1944. As a high ranking official in the Ministry of Education after the war, he was involved in significant and controversial education reform before being arrested by the secret police in 1953 and held for three years under appalling conditions, sometimes in solitary confinement, in Recsk—the worst of the Gulag-style camps in Hungary.

He studied mathematics, physics, and philosophy at the University of Debrecen, graduating in 1944. He obtained a first PhD (with highest honors) from the Eötvös Collegium in 1947—this for a thesis on the sociology of science that he later insisted was worthless. After leaving Hungary in 1956, he obtained a Rockefeller Foundation grant to study for a second PhD at the University of Cambridge. From 1959 onward he regularly attended Karl Popper's seminar at the London School of Economics (LSE). Popper became the most important influence on him; amongst other things, Popper's Open Society views reinforced the decline of his faith in Marxism that had begun in 1956. Lakatos accepted a lectureship in logic at LSE in 1960 and was promoted to a personal chair (in Logic, with special reference to the philosophy of mathematics) in 1970. He was only fifty-one years old and still teaching at LSE at the sadly early time of his death from a heart attack in 1974.

### PHILOSOPHY OF MATHEMATICS

Lakatos's Cambridge PhD thesis became the basis for his *Proofs and Refutations*. This work, published initially in the form of journal articles in 1963–1964 and in book form only posthumously in 1976, constitutes his major contribution to the philosophy of mathematics. A dialogue between a group of frighteningly bright students and their teacher, it reconstructs the process by which Euler's famous conjecture about polyhedra (that they all satisfy the formula: number of vertices plus number of faces minus the number of edges equals two) was proved and, in the process, heavily modified and transformed.

Lakatos's claim was that although the eventual proof of the theorem in mathematics may be cast as a straightforward deduction, the process by which the proof is found is a more exciting process, involving counterexamples, reformulations, counterexamples to the reformulations, and careful analysis of failed proofs leading to further modifications of the theorem. Any number of interesting claims about both the history and philosophy of mathematics are thrown in to the mix—sometimes in the main text, sometimes in one of the voluminous footnotes. The work is a literary tour de force.

The extent to which *Proofs and Refutations* represents a distinctive epistemological view that might challenge more traditional accounts in the philosophy of mathematics, such as logicism or formalism, is a controversial one. Lakatos sometimes described himself as extending Popper's fallibilist-falsificationist view of science into the field of mathematics, and there are even hints of Lakatos's Hegelian past in some of the claims about the autonomous development of mathematics. An alternative view, however, is that the main significance of his work is to cast light simply, though importantly, on the development of mathematics—on how mathematical truth is arrived at—and that it has nothing distinctive to say about the epistemological status of mathematical truths once they have been arrived at. But even if this alternative view is correct, there is a good of undoubtedly epistemological significance in some of the particular issues raised (for example, what he calls the problem of translation highlighting issues about how the formal systems, within which effectively infallible proof can be achieved, relate to the informal mathematics said to be captured by those formal systems).

### PHILOSOPHY OF SCIENCE

As indicated, Lakatos thought of himself for some years as extending Popperianism, developed as an account of natural science, into the seemingly unlikely field of mathematics. However, he eventually began to discern faults in Popper's philosophy of natural science. Most significantly, in comparing Popper's views with those of Thomas Kuhn, Lakatos came to realize that Popper's view on the way that evidence impacts on scientific theories is seriously awry.

Lakatos claimed that science is best viewed as consisting not of single, isolated theories but rather of broader research programs. A hard core of principles characterizes such a program, but this needs to be supplemented by an evolving protective belt of more specific and auxiliary assumptions in order to come into contact

with experiment. When the latest theory produced by a program proves to be inconsistent with some empirical result, then the standard response of the program's proponents will be to retain the hard core and look to modify some element of the protective belt. This is a process much closer to Kuhn's idea of adverse experimental results being treated as anomalies than to the standard Popperian idea of falsification. However, while Popper used his framework to defend the idea that theory-change in science is a rational process, Lakatos believed that to accept Kuhn's account of paradigms and paradigm shifts was in effect to abandon the view that the development of science is rational. Kuhn's view, he (in)famously claimed, makes theory-change a matter of mob psychology. He was therefore led to make the important distinction between progressive and degenerating programs. The latest Newtonian theory was inconsistent with observations of Uranus's orbit; Newtonians reacted not by giving up the basic theory but by postulating a new planet.

Philip Gosse (1810–1888) realized that claim that God created the world essentially as it now is in 4004 BC is inconsistent with what Darwinians believed to be the fossil record; Gosse reacted not by surrendering the basic creationist theory (hard core), but by postulating that the alleged fossils were parts of God's initial creation. The first was a great scientific success; the second bears the clear hallmark of pseudoscience. Why? Lakatos's answer is that the Newtonian shift was progressive: It not only solved the anomaly of Uranus but made extra predictions (of the existence of a new and hitherto unsuspected planet) that could be tested empirically and were indeed confirmed (by the discovery of Neptune). Gosse's shift is degenerating: All it does is reconcile the basic creationist theory with observation but permits no independent test. The development of science consists of the replacement of degenerating programs by progressive ones. There are many other interesting aspects of the methodology, particularly concerning the role of heuristic principles, and of whether it does satisfactorily save the rationality of science.

## LALANDE, ANDRÉ

(1867–1964)

André Lalande, the French philosopher, was born in Dijon and entered the *École Normale Supérieure* in 1885. He took his doctorate in 1899 and taught in *lycées* until he was appointed first to a lectureship and then, in 1904, to a chair of philosophy at the University of Paris.

Lalande was a rationalist whose whole life was devoted to the cause of international communication and the dissemination of knowledge. His constant preoccupation after 1902 was the launching, and subsequent reediting, of the *Vocabulaire technique et critique de la philosophie*, which aimed at the concise definition and standardization of philosophical terminology. His own philosophical work corresponds to this recognition and promotion of an interdependent humanity.

In his thesis of 1899, *L'idée directrice de la dissolution opposée à celle de l'évolution*, Lalande challenged Herbert Spencer's thesis that progress is evolutionary and differentiating, and held that, on the contrary, dissolution—or, as he later called it, involution—is more widespread and significant. Involution, or movement from the heterogeneous to the homogeneous, is observable in nature as entropy, or increase of randomness. In human life, however, this movement toward uniformity is fruitful and is served by reason, which, in scientific investigation, leads to the progressive subsumption of more and more classes of phenomena under fewer general laws.

Lalande disapproved of an imposed uniformity, which represents merely the transference from the indi-

vidual to the group of evolutionary, divisive drives. True reason ensures that although people feel differently, they shall think in the same way and thus understand each other even when they do not resemble each other. Lalande's concern was for the individual, whose uniqueness is sacrificed to function in a rigidly specialized and differentiated society. The application of reason to life in the technological field liberates the individual from his functional role, and the application of reason in the cultural field enables men to afford, and to benefit from, the diversity that is their birthright.

In *La raison et les normes* Lalande restated his involuntarist case in the light of recent philosophies of "being-in-the-world." He took cognizance, for example, of the argument that geometrical, objective space is derived from the neuromotor "spaces" of man facing his tasks, but for Lalande the superiority of a common space amenable to conceptualization remained unimpaired. Similarly, he preferred chronological time to the "real" time of naive emotional experience. Lalande reaffirmed his universalist conception of rationality against more recent phenomenological thinking.

## LAMARCK, CHEVALIER DE (1744–1829)

Jean Baptiste Pierre Antoine de Monet, Chevalier de Lamarck, the French biologist and formulator of the first

comprehensive theory of evolution, was born at Bazentin-le-Petit, a village in northeastern France. As a youth he studied briefly for the priesthood, but later withdrew to follow the family tradition of army service. While in Paris recovering from an injury and intermittently studying medicine, he met Jean-Jacques Rousseau, through whom he became interested in botany. This interest led to investigations that culminated in the publication of a large work on the flora of France, which brought Lamarck immediate fame and election to the Academy of Sciences. From 1783 to 1793 he held a small post at the Jardin du Roi, which was reorganized and expanded along lines proposed by Lamarck to include a museum of natural history and twelve professorial chairs. The last of these, for the study of invertebrates, went almost by default to Lamarck himself. Hence, at the age of fifty he began his indefatigable labors as a zoologist. These labors led to his conclusion, at some time between 1794 and 1802, that a transmutation of animal species had taken place. He expounded his views in a succession of important works: *Système des animaux sans vertèbres* (Paris, 1801), *Recherches sur l'organisation des corps vivans* (Paris, 1802), *Philosophie zoologique* (2 vols., Paris, 1809–1830, translated by H. Elliot as *Zoological Philosophy*, London, 1914), and *Histoire naturelle des animaux sans vertèbres*, (7 vols., Paris, 1815–1822). The significance of Lamarck's contribution was scarcely appreciated by his contemporaries. When he died at the age of eighty-five, blind and poor, he had become a forgotten man. His body was buried in a pauper's grave whose exact location is unknown.

## SYSTEM OF NATURE

Lamarck aspired to produce a large-scale "system of nature" set in a deistic framework. He held that nature, "the immense totality of different beings," is neither eternal nor self-explanatory. It is the creation of a "Supreme Author" who brought matter into being and instituted the world order by means of laws that govern whatever happens. Within nature, change is universal. But nature in toto is unchangeable and "should be regarded as a whole constituted by its parts, for a purpose which its Author alone knows." This whole, however, is as distinct from the Creator as a watch is from the watchmaker. Hence, nature has productive powers of its own that the sciences can properly interpret in mechanical and materialistic terms. The system that Lamarck originally planned was to have included sections on physics, chemistry, meteorology, geology, and biology. Some of his writings did, in fact, discuss all these topics, but what

appeared can hardly be said to form a unified scheme. His attention was increasingly occupied by his reflections on living things, the science of which he named biology in 1802.

## EVOLUTION

Lamarck effected a breakthrough to an evolutionary conception of nature by bringing together several lines of thought. His geological studies convinced him that Earth had endured for an immense span of time, during which it had undergone many changes of a gradual sort, especially in its surface features. His observation of fossils supported the conclusion that animal life had existed for a large part of geological time and had also undergone gradual changes. Hence, species must be mutable, and their apparent stability is due to man's limited time perspective. Furthermore, organisms are simply physical bodies whose parts are highly organized. Thus, Lamarck was opposed to vitalism. "Every fact or phenomenon observed in a living body," he held, "is ... a physical fact or phenomenon, and a product of organization" (*Histoire naturelle des animaux sans vertèbres*, Vol. I, p. 53). Accordingly, he accepted the conclusion that a "spontaneous generation" of organisms had occurred. Animals and plants represent two independent lines stemming from two distinct types of spontaneous generation that utilized chemical materials differently. These materials are wholly inanimate and display none of the characteristic properties observed in the organisms they constitute.

## PERFECTING POWER IN NATURE

The history of living things on Earth reveals a steady increase in the complexity of their organization, a process by which they have also been perfected. "Nature has produced all the species of animals in succession, beginning with the most imperfect or simplest, and ending her work with the most perfect." Man is the being who exemplifies the highest excellence of bodily organization, and he thereby provides "the standard for judging the perfection or degradation of other animal organizations." Lamarck's thought at this point was influenced by the idea of the "great chain of being," the infinitely graded series of forms from highest to lowest, which was a doctrine congenial to eighteenth-century deism. Since, in his evolutionary approach, the series came into existence from the bottom, Lamarck attributed it to a perfecting power inherent in nature. The postulating of this perfecting power is the feature of Lamarck's evolutionism that separates it most sharply from that of Charles Darwin.

## CAUSES OF THE POWER OF EVOLUTION

If the environment were unchanging, the perfecting power of nature would produce a simple, linear sequence of organisms. But the environment is ceaselessly changing, and, as a result, evolution is "deflected" from a linear path into the "branching" pattern actually found among plants and animals. The mechanism by which the branching pattern is formed consists of a group of causal factors often mistakenly supposed to be the whole of Lamarck's theory, instead of just a part of it.

The causal factors are specified in several "laws"—two in *Philosophie zoologique* and four in *Histoire naturelle des animaux*—whose purport can be summarized as follows. The organs and habits by which animals maintain their adaptation to the environment are controlled by bodily fluids that are constantly in motion. Animals whose structure is so elementary that they have no faculty of feeling are acted on mechanically by environmental changes. New motions of the internal fluids are set up, and these give rise to adaptive alterations in the organs and habits. The case is different with animals whose structure is complicated enough to enable them to feel wants or needs (*besoins*). When the environment of these animals changes, new needs are felt, and each need, "exciting their inner feeling (*sentiment intérieur*), forthwith sets the fluids in motion and forces them toward the point of the body where an action may satisfy the want experienced" (*ibid.*, p. 185). If a suitable organ already exists at that point, it is immediately incited to action. If not, the felt need gradually causes the organ to be generated, "provided the need be pressing and continuous." Everything thus acquired by an individual animal during its lifetime is preserved by heredity (*génération*) and transmitted to that individual's progeny. The operation of these causal factors, superimposed on the general perfecting tendency of nature, accounts for all that has happened in evolution.

## MAN

Man's place in this theory was a topic that Lamarck understandably treated with caution. He stressed man's "extreme superiority" over other living things because of his possession of reason, although anatomically he differs only in degree from monkeys and apes. Is it not plausible to suppose that the differences have been "gradually acquired" over a long period of time? "What a subject for reflection," Lamarck commented, "for those who have the courage to enter into it!" He himself dared in a short section of *Philosophie zoologique* to outline a hypothetical

explanation of how apelike beings might “at length be transformed” into manlike beings, able to walk upright, to use tools, and to develop “the marvelous faculty of speaking.” Throughout the process, changed habits would produce new wants and new capacities, until true human beings appeared. “Such are the reflections which might be aroused, if man were distinguished from animals only by his organization, and if his origin were not different from theirs.” At this point Lamarck’s courage apparently gave out.

## ASSESSMENT

Despite the comprehensiveness of his outlook, Lamarck failed to formulate a unified theory of evolution. Therefore, he had to conclude that the diversification of plants and simple animals was due to mechanical factors alone, whereas in the case of complex animals an important psychological and teleological factor was operative. He held that no species had ever been totally extinguished, in spite of what the fossil evidence indicated, because he believed that the plan of the Supreme Author of the universe would not allow such wastage. His acceptance of the perfecting tendency obliged him to affirm that there are really two animal series: the grand one from simple to complex, and the particular, branching series that have deviated from it. Above all, his theory demanded not only that modifications acquired by parents during their lifetime should affect their offspring, but also that they should affect the same parts in the offspring as in the parents and should become a permanent hereditary feature in that line of descent, regardless of later modifying factors. Modern genetic research has shown strong, although perhaps not conclusive, reasons for believing that such an “inheritance of acquired characteristics” cannot occur. None of these difficulties, however, can detract from the greatness of Lamarck’s contribution. “He first did the eminent service,” Darwin remarked, “of arousing attention to the probability of all change in the organic world being the result of law, and not of miraculous interposition.”

## LAMBERT, JOHANN HEINRICH

(1728–1777)

Johann Heinrich Lambert, the German mathematician, physicist, astronomer, and philosopher, was born in Mulhouse, Alsace. He taught himself mathematics, philosophy, and Asian languages; after 1748 he served as tutor in a Swiss family, traveling about Europe with his pupils for several years. He became a member of the Munich Academy in 1759 and of the Berlin Academy in 1764. In 1765 he was appointed by Frederick II as Prussian surveyor of public works. He did research in heat, light, and color and was the founder of the science of photometry. In mathematics Lambert demonstrated that  $\pi$  is an irrational number, and he introduced the conception of hyperbolic functions into trigonometry. In his *Kosmologische Briefe über die Einrichtung des Weltbaues* (Cosmological letters on the structure of the universe; Augsburg, 1761), Lambert proposed a cosmogonic hypothesis based on Isaac Newton’s theory of gravitation; it was similar to the nebular hypothesis proposed earlier by Immanuel Kant in his *Allgemeine Naturgeschichte und Theorie des Himmels* (Königsberg and Leipzig, 1755) but unknown to Lambert.

Lambert’s *Neues Organon, oder Gedanken über die Erforschung und Bezeichnung des Wahren und dessen Unterscheidung von Irrtum und Schein* (New organon, or thoughts on the investigation and indication of truth and of the distinction between error and appearance; 2 vols., Leipzig, 1764) was an attempt to reform Wolffian logic. It was strongly influenced by the logical treatises of the Pietist philosophers A. F. Hoffmann and C. F. Crusius, and like their work it widened the field of logic to cover psychological and methodological questions. Although Lambert believed that metaphysics should follow a mathematical method, he assumed, like the Pietists and John

Locke, a multiplicity of elementary notions. The a priori sciences (pure theoretical and practical philosophy) should be constructed by combining these elementary notions mathematically. The final section of the *Neues Organon* discusses appearance and gives a theory of experimental and probable knowledge. It contains rules for distinguishing false (or subjective) appearance from true (or objective) appearance, the latter arising from true perception of the phenomenal world. As a blend of Leibnizian, Wolffian, Lockean, and Pietist elements the *Neues Organon* was neither more original nor more influential in its time than several Pietist treatises on logic or J. B. Basedow's *Philalethie*.

The lesser-known *Anlage zur Architektonik, oder Theorie des Einfachen und Ersten in der philosophischen und mathematischen Erkenntnis* (Foundation of architectonic, or theory of the simple and primary elements in philosophical and mathematical knowledge; 2 vols., Riga, 1771) was a much more important work. In this work Lambert, dissatisfied with classical German and particularly Wolffian metaphysics, proposed a far-reaching reform through an analysis of the sources, genesis, and development of the basic concepts and axioms of metaphysics and their interrelations. Reacting also against sensationalism, skepticism, and the new schools of commonsense and popular philosophy, Lambert wished to save metaphysics by presenting it in a phenomenalist manner (as J. N. Tetens and Kant were to do later).

Following Locke, Lambert assumed a certain set of concepts as given and then examined them. Once the analysis was completed, Lambert held, it would be possible to change from an empirical to a rationalistic procedure—the a priori deductive construction, modeled on the procedures of mathematics, of a body of general sciences that are true both logically and metaphysically. The deduced propositions of these sciences would then be applied to experience in the manner of applied mathematics. The joining of such propositions with rules abstracted from observation and experiments would give a foundation for truth in each of the particular sciences.

There were thus two main aspects to Lambert's philosophy, the analytic and the constructive. The former was the predominating interest in the *Anlage zur Architektonik*. This work consists largely of detailed discussions of, and subtle distinctions between, many of the most common simple notions and axioms and elementary interrelations discussed in traditional metaphysics. This refined analysis, too detailed even to be sampled here, exerted a great influence on Tetens's mature work and on the making of Kant's *Kritik der reinen Vernunft*. Kant had

earlier been much impressed by the *Neues Organon*, and acknowledged to Lambert in correspondence his interest in Lambert's analyses.

The second, constructive, aspect of Lambert's philosophy was an attempt to develop a mathematical logic (or "intensional calculus") for deducing propositions by an easy and exact method from the simple notions and axioms, once they have been established analytically.

## LAMENNAIS, HUGUES FÉLICITÉ ROBERT DE (1782–1854)

Hugues Félicité Robert de Lamennais, the French ecclesiastic and philosopher, was born in Saint-Malo, Brittany, and died in Paris. Lamennais received the tonsure in 1809 but was not ordained a priest until 1816. His early works in defense of ultramontanism won him the approval of Rome, but it was not long before his inability to compromise in the interest of expediency led to his condemnation. Although never excommunicated, he voluntarily

relinquished all sacerdotal functions and died after refusing the last rites.

### ULTRAMONTANISM

Lamennais's first influential work, *De la tradition de l'église sur l'institution des évêques* (Paris, 1814), written in collaboration with his brother Jean, was an attack on Gallicanism. Directly inspired by Vicomte de Bonald, it propounded three theses—the supremacy of the Church of Rome, papal infallibility in matters of doctrine, and the basic authority of tradition. It did not, however, grant the pope any sovereign rights in temporal matters. Lamennais's second work, the *Essai sur l'indifférence en matière de religion* (1817–1823) was welcomed enthusiastically in Catholic circles and received the approval of Leo XII. It took as its premises that no beliefs are without influence on the welfare of society and that religious beliefs are of primary importance in this respect. Hence, no man has the right to be neutral in religious disputes. Neutrality may arise from false notions of religion's place in life, from a failure to distinguish between orthodoxy and heresy, or from ignorance, lack of serious purpose, or simple sloth. Since no one can rightly maintain two antithetical ideas, there can be only one religious truth, one mouthpiece for it, and one tradition.

### TRADITIONALISM

The traditionalism involved in this led to Lamennais's denial of the individual's rational powers, a denial that he clung to consistently. Our senses, feelings, and reason may lead to the truth, but only accidentally. Certitude can be acquired only by the common reason, that of the human race. One must therefore fuse his opinions with those of his fellow men and find the solution to his problems in faith, authority, and common sense. Trust in one's own insight is madness, as is eccentricity of behavior. But if one asks whence comes the authority of the general reason, the answer is, from God. God has entrusted it to the church, which speaks through the pope. No individual philosopher, even though he be a Descartes, can substitute his method for that based on revelation.

### THE CONDEMNATION

So extreme a form of ultramontanism may have been logical, granted its premises, but it was politically inexpedient. Its anti-Gallicanism alone would have aroused resentment, but it was coupled with violent attacks on the French university system, the Charter, and certain personalities, such as Comte Denis de Frayssinous. Lamennais paid little attention to his critics, turned from them

to the Vatican, and was shocked to receive in 1832 the encyclical *Mirari Vos*, which, without mentioning him by name, nevertheless condemned his ultramontanism on the ground that it disrupted the existing harmony between church and state. At the same time, it condemned freedom of conscience and opinion, which could lead only to freedom to err. Lamennais submitted but restricted his submission to questions of religion. During this period he also published his *Paroles d'un croyant* (1834), a series of prose poems that preached fraternity, freedom of association, and confidence in God and in prayer. This work was condemned outright in the encyclical *Singulari Nos* (1834).

### PHILOSOPHY

In substituting “the Christianity of the human race” for that of the Vatican, Lamennais retained his traditionalism but abandoned his ultramontanism. His point of view was expressed in a three-volume work, the *Esquisse d'une philosophie* (1840), of which he published a fourth volume in 1846. It began with a theology, continued through a philosophical anthropology, aesthetics, and philosophy of science, and was to have been completed with a social philosophy. Lamennais's theology was Trinitarian and made the three persons of the Deity power, intelligence, and love, all interfused. Each realm of being reflected this triune nature, which was undemonstrable but demanded by the very nature of human thought. The work as a whole developed this thesis.

Lamennais's philosophy was Christian traditionalism minus ecclesiasticism, but with a philosophy of nature added. No man, he held, can assent to his own deductions if they are not in harmony with those of the whole human race, and the opinions of the human race will be found in tradition. The inconsistencies of tradition were never dwelt upon. His *Esquisse*, because of its Christian overtones, had no popularity in republican circles and, as for his Catholic associates, they felt little if any need for it.

## LA METTRIE, JULIEN OFFRAY DE (1709–1751)

Julien Offray de La Mettrie, the French physician and philosopher, was born in Saint-Malo, Brittany. After attending the Collège d'Harcourt, he studied medicine at the University of Paris, finally obtaining his doctor's degree from the Faculty of Rheims in 1733. He next went to Leiden to complete his training under the celebrated Dr. Hermann Boerhaave, whose iatromechanist doctrines were to have a decisive influence on his orientation in the philosophical, no less than in the medical, domain. Back in Saint-Malo as a practicing physician, La Mettrie undertook to popularize Boerhaave's teachings by translating into French a number of the latter's principal works. His marriage in 1739 to Marie-Louise Droneau proved unhappy and led before long to a separation. From 1743 to 1745 La Mettrie, as surgeon to the *Gardes Françaises* regiment, participated in several campaigns of the War of the Austrian Succession. The publication in 1745 of his first philosophical work, the *Histoire naturelle de l'âme*, brought him under severe official censure for his materialist views. This circumstance, along with an imprudent satire he wrote on the foibles of his medical colleagues, caused La Mettrie to exile himself to Holland. It was there that he published in 1747 *L'homme machine*, his best known and most influential book, whose atheistic and materialistic contents aroused even the liberal-minded Dutch to angry protest.

La Mettrie was fortunate enough, at this crucial moment, to find a protector in Frederick the Great, who invited him to Berlin. In Prussia he was appointed a member of the Royal Academy of Sciences, as well as "physician ordinary" and "reader" to the king. Profiting from the security of his position, he brought out, among other writings, *L'homme plante* (1748), *Le système d'Épicure* (1750), and *Discours sur le bonheur* (1750), each of which attested, in its own way, to the sort of scandalizing unorthodoxy of thought for which their author had already acquired a unique reputation. His numerous enemies, powerless to suppress either him or his ideas, contented themselves with a plethora of refutations that were too often irrelevant in substance or abusive in tone; in particular, they drew a portrait of La Mettrie himself as a monster of depravity. But apart from his theoretical advocacy and personal pursuit of a frankly hedonistic ideal and his delight in provoking or shocking those of a stiffly bourgeois or pious outlook, La Mettrie's character was actually far from deserving the ignominy heaped upon it. He died in 1751 of what was regarded by his contemporaries, somewhat unkindly, as the effects of overeating—a diagnosis exploited by his foes to prove both the practical dangers of materialism and the providential punishment reserved for atheists. Frederick II composed the eulogy that was read before the Berlin Academy. Besides his philosophical works, La Mettrie wrote several medical treatises of only minor value, a series of polemical and ironical pamphlets aimed at his critics, and three mordant, informative satires on what he considered to be the incompetence and "malpractice" of the doctors of the period, the best being his *Machiavel en médecine* (1748–1750).

#### "THE HISTORY OF THE SOUL"

In the *Histoire naturelle de l'âme*, directed against the metaphysical dualism of René Descartes, Nicolas Malebranche, Gottfried Wilhelm Leibniz, and their followers, La Mettrie contended that the soul owes its being to those specific organic forms, produced by a *force motrice* inhering in matter, on which the mental faculties and operations remain dependent. The "history of the soul" thus becomes an aspect of the body's history and falls under the authority, not of the metaphysician or theologian, but of the natural scientist. In this claim we have the fundamental attitude of La Mettrie, from which his originality as a philosopher would spring. His method of inquiry consisted in moving regularly from the empirical sphere of scientific facts and theories to that of philosophy proper—the latter being regarded, at least with respect to

epistemological and psychological problems, as the logical extension of such branches of knowledge as anatomy, physiology, chemistry, medicine, and the like. La Mettrie was perhaps the first “medical” philosopher in the complete and true sense—a designation suggesting at once the strengths and weaknesses peculiar to his thought.

In the *Histoire de l'âme*, La Mettrie sought to substantiate his naturalistic conception of the soul by means of two types of evidence, profusely cited, which tend to complement each other. Drawing, on the one hand, from the common fund of Lockean sensationalism (to which he gave, incidentally, a materialist meaning), La Mettrie argued that the contents of the mind—hence the mind itself—have no reality independently of the natural world in which sense impressions originate or of the sense organs by which these are transmitted. Utilizing, on the other hand, the technical data offered by the medical sciences of his time, he affirmed that the sensitive and intellectual activities of what is conventionally called the soul depend essentially on the structure and functions of the central nervous system, in general, and of the brain, in particular. Establishing a natural continuity from the external world through the sensory apparatus to the brain itself, La Mettrie identified the soul with a physically conditioned process in a way that allowed him to explain the various faculties of the soul, such as memory, reflection, imagination, the emotions, judgment, volition, solely in terms of their related organic causes.

However, a special feature of the *Histoire de l'âme* was its exposition of materialism within the conceptual framework of Aristotelian metaphysics. La Mettrie speculated that it is by virtue of the appropriate “material forms” and “substantial forms” that matter, actively organized by an intrinsic *force motrice*, realizes its potential attributes of a “vegetative soul” and a “sensitive soul”; each of these, in turn, he makes the “directing principle” of the biological or psychological functions coming under its sway. In presenting his empirico-physiological theory of mind under Scholastic auspices, La Mettrie intended, no doubt, to lend it some measure of metaphysical support, but probably more important was his wish to disarm the censorship by insisting—as he did throughout—on his theory’s conformity with the prevailing orthodox tradition in Western philosophy. His strategy did not succeed very well, however, for the Aristotelianism on which he grafted his opinions served only to render them obscure and confused, yet apparently not quite obscure enough to prevent the authorities from recognizing and suppressing his “heretical” defense of materialism.

## MAN A MACHINE

The thesis of *L'homme machine*, in asserting and illustrating the material dependence of the states of the soul uniformly on the corresponding states of the body, remains similar to that of the *Histoire de l'âme*, but its mode of expression and exact meaning are appreciably different. Composed in a lively, unmethodical, popular fashion, its exposition of materialism is effected not only without any metaphysical substructure but in a definitely antimetaphysical spirit. Its naturalistic view of man, consequently, is offered mainly as a general heuristic hypothesis necessary in the positive study of behavior, without the need being felt, beyond such a standpoint, to make mental processes reductively identical with their physiological causes. Concurrently La Mettrie proposed an experimental-inductive method, as opposed to the then prevalent apriorist ones, in the search for the principles of psychology. Discussing the organic basis of both vital and psychic events, he insisted on the mechanistic character of the causation involved. This important point was not brought out clearly in *Histoire de l'âme* because of the attempted materialization of the pseudo-Scholastic “souls” and “faculties.”

In *L'homme machine* no essential distinction remained between the conscious and voluntary, as against the merely vital, involuntary, or instinctual activities of the “human machine”; the two types of activity are presumed explainable by the relative complexity of the mechanical structures responsible for their production. Thus La Mettrie could claim that his man-machine theory was the extension to its logical and empirical limits of the Cartesian animal-automaton doctrine. However, he must be credited with conceiving of the “living machine” in a manner that goes beyond the inadequacies of Descartes’s passive and inert notion of mechanism. The organic machine that sustains the sensitive and mental life of the individual is defined by La Mettrie as a purposefully self-moving and self-sufficient system, consisting of dynamically interrelated parts. It was typical of his empirical procedure that he found proof of the autonomous energy and internal finality of the organism in the physiological data of irritability. Following the pioneering researches of Albrecht von Haller, La Mettrie was among the first to understand the radical value of the capacity for irritability, and he succeeded in interpreting it with particular relevance for his thesis of psychophysical automatism.

Among the subsidiary themes of *L'homme machine*, the declaration of atheism was a new and significant development. On the one hand, it served a polemical and

propagandist aim against the religious enemies of La Mettrie's philosophical position. On the other hand, it was a logical outcome of the universal naturalism in which the man-machine theory was appropriately framed; the traditional belief in an Intelligent Creator was replaced by the concept of an active, self-creating nature.

In epistemology, La Mettrie's characteristic approach was to offer picturable analogies between mind and brain, suggesting (however crudely) the model of a "thinking machine" into which sense perceptions feed ideas in the form of coded symbols that are, in turn, stored, classed, compared, and combined by the cerebral apparatus in order to engender all the known varieties of thought. This mechanical ordering and manipulation by the brain of its symbolically represented contents prompted La Mettrie to consider that the fundamental faculty of the mind is "imagination."

Another feature of *L'homme machine* is its persistent tendency to assimilate human to animal nature with the aid of evidence drawn from the spheres of comparative anatomy and experimental psychology. The doctrine of free will, of course, becomes meaningless in the light of physiological necessity. The moral aspect of behavior is regarded as no less determined than its other aspects, although it should be noted that the man-machine theory, despite its context of universal determinism, leads to the affirmation of a hierarchy of individual values and capabilities, inasmuch as no two "machines" could ever be identical or equal. The problem of the moral or intellectual perfectibility of man, within the compass of La Mettrie's materialism, becomes primarily a medical problem, for its solution depends on the possibility of perfecting the state of the organism.

## DISCOURSE ON HAPPINESS

In the *Discours sur le bonheur*, intended as a refutation of Senecan Stoicism, La Mettrie viewed the *summum bonum* of happiness in a manner no less individualistic than hedonistic. In consistence with his materialist premises, he described happiness as the optimum state of pleasurable well-being of the "man-machine." Underlying his entire treatment of the subject is the assumption that happiness was destined by nature as a benefit to be enjoyed by each and every person, regardless of moral, intellectual, or social preconditions of any sort; that is, the goal of happiness is divorced basically from such traditional considerations as vice and virtue, ignorance and knowledge, social status and responsibility. La Mettrie obviously conceived of the problem of happiness, seen from the perspective of medical ethics, as similar to—

indeed, as a special instance of—the more comprehensive problem of health. Accordingly, he diagnosed the greatest threat to felicity to be "remorse," a morbid and "unnatural" symptom, which he proposed, ever faithful to the Hippocratic oath, to alleviate in all and sundry, including even conscience-ridden criminals; he remarked that the practical control of social behavior was a political matter and no business of his.

The *Discours sur le bonheur* was misinterpreted as a cynical inducement to vice and crime and, more than any of his works, gave to the author an enduring reputation for immoralism among philosophes and antiphilosophes alike.

## MINOR WORKS

Among La Mettrie's minor works, perhaps the most curious is the *Système d'Epicure*. Its concern with ontogenesis and the origin of species represented a broadening of La Mettrie's materialism into an area of biological speculation which, at the time, was just beginning to excite interest. But his description of the "evolutionary" process, in which monstrous and unviable productions are supposed to have been eliminated in favor of the well-constituted types now extant, did little more than revive Lucretian memories.

In *L'homme plante*, La Mettrie's purpose was to stress the various parallelisms of structure and function between two such seemingly disparate things as the human organism and vegetable life. Reflecting his strong taste for analogical reasoning, it is an extreme confirmation of the "chain-of-being" idea, which it interprets in the sense of a uniform destiny for man and for all other living forms, excluding the possibility of a spiritual transcendence of nature.

*Les animaux plus que machines* is mainly a polemical piece directed against the school of animistic biology. By elaborating a mock defense of the opinion that a "soul" governs the animal economy, La Mettrie managed to expose, with the support of much physiological evidence, the absurdity and uselessness of such a hypothesis. The inference is that it would be equally ridiculous to claim that the operations of the human machine presuppose the agency of a "soul."

La Mettrie's philosophy, and in particular the man-machine doctrine central to it, has, owing to its very character, grown somewhat obsolete, together with the scientific documentation to which it was so intimately linked. The specific features of his mechanistic theory of mind might, in relation to what is now known or still

unknown about neural processes, seem naive, crude, superficial, and pretentious. Nevertheless, his was the first naturalistic rationale for, and technical application of, a consistently physiological method in psychology. And while his philosophic contribution remains circumscribed by the biomedical standpoint that shaped his thinking, the man-machine hypothesis may be said, within its proper limits, to have retained a basic validity and vitality. Despite La Mettrie's bad name in his own age, and the many attempts to suppress, disfigure, or discredit his ideas, he exerted (surreptitiously, on the whole) a considerable influence in the eighteenth-century milieu. Among those indebted to the man-machine conception and to the naturalistic overtones and consequences that accompanied its formulation, the most important were Denis Diderot, Baron d'Holbach, and Pierre-Jean Georges Cabanis. Long neglected after his death, La Mettrie has been recognized since the latter part of the nineteenth century as one of the major forerunners of modern materialism. His nonreductive form of materialism may be regarded as an early version of a theory that is widely advocated at the present time by, among others, Ernest Nagel and various American naturalists; and his view that human beings can be fruitfully considered as a certain type of machine has obvious similarities to the principles underlying the science of cybernetics.

## LA MOTHE LE VAYER, FRANÇOIS DE (1588–1672)

François de La Mothe Le Vayer, a French skeptical philosopher, was born in Paris, the son of a government official. He acquired his father's post when the latter died in 1625. His wife was the daughter of a Scottish intellectual, Adam Blackwood. During his early years La Mothe Le Vayer traveled widely in Europe. In 1639 he was elected to the Académie française and in 1647 was appointed preceptor to the Duke of Orléans. He was a prominent figure in avant-garde circles in Paris—in the group around Michel Eyquem de Montaigne's adopted daughter, Mademoiselle De Gournay; in the group of *libertins érudits* with Gabriel Naudé (1600–1653), Guy Patin (1601–1672), and Pierre Gassendi; in the scientific group around Marin Mersenne; and in the literary world of Molière (1622–1673; who jested at La Mothe Le Vayer in

*Le Mariage forcé* and other plays) and Savinien de Cyrano de Bergerac. His many writings on skepticism began with *Dialogues d'Oratius Tubero* (1630), followed by the *Discours chrétien de l'immortalité de l'âme* (1637, the year of René Descartes's *Discours de la méthode*), *De la Vertu des payens* (1642, published with Cardinal de Richelieu [1585–1642] as the sponsor), and a long series of skeptical essays on history and culture throughout the rest of his life.

Although his views are based primarily on those of Sextus Empiricus (whom he calls “le divin Sexte” and the author of “notre décalogue”) and Montaigne, La Mothe Le Vayer's skepticism represents perhaps the most extreme type of antirationalism in the seventeenth century. He continually offers a wealth of evidence to show the variations in human moral behavior, the diversity of people's religious beliefs and practices, the vanity of scientific study, and the virtues of skepticism. He rarely develops his case theoretically by means of systematic arguments. Instead, he usually offers only illustrative materials, followed by a fideistic message that man can find truth only through faith, not through the use of his reason and senses.

In *Petit Traité sceptique sur cette façon de parler, n'avoir pas le sens commun* (1647) La Mothe Le Vayer contends that man does not understand the nature of even the most obvious things. All of one's information is relative to one's faculties. Even if there are any instruments for finding the truth about things, one, unfortunately, is unable to discover them. One's senses are unreliable, and one lacks any guaranteed criterion for distinguishing veridical experiences from others. Indubitable truths can be known only in heaven, not here and not through any human science.

These views are further developed in his *Discours pour montrer que les doutes de la philosophie sceptique sont de grande usage dans les sciences* (1669), where it is claimed, as the title shows, that the great service of Pyrrhonian skepticism for the sciences is that it can eliminate any serious concern with scientific research and that such research is a form of blasphemy. He asserts, without offering any real arguments, that logic is unreliable and physics only a problematical subject about which there are conflicting opinions. Nature is the free manifestation of God's will. Therefore, any attempt to restrict God's achievement to what man can measure and understand is an attempt to limit God's freedom and is hence blasphemous. When the scientists realize how uncertain their disciplines are, they should give them up and adopt

skepticism, “the inestimable antidote against the presumptuous knowledge of the learned ones.”

This complete skepticism should undermine the dogmatist's confidence and pride and lead him or her to the true faith: Christianity. In *La prose chagrine* (1661) La Mothe Le Vayer proclaims that of all the ancient philosophies, “there is no other that agrees so easily with Christianity as skepticism, respectful towards Heaven and submissive to the Faith.” Had not St. Paul preached that skepticism was the way to salvation? The true Christian skeptic leaves his or her doubts at the foot of the altar and lives by faith.

La Mothe Le Vayer's anti-intellectual and destructive attack on human rational knowledge (presented almost obviously to the scientific revolution going on around him, and especially to the achievements of Descartes) and his appeal to faith, although not introducing much that was new to skeptical argumentation, carried the Montaignian position to an absurd extreme. He denied any and all value to intellectual activities and left only blind faith. As a result, many commentators from Antoine Arnauld on have assumed that he was a pure libertine, undermining all bases for religion, and have classified him, partly on the basis of his risqué work *Hexaméron rustique* (1670), as an *incrédule voluptueux* (sensual non-believer). His views, however, are compatible with his having been either a sincere Christian skeptic or a secret atheist undermining confidence in all views and beliefs—a genuine fideist or an irreligious doubter. His philosophical influence seems to have been more through personal contact than through any serious presentation of philosophical skepticism. As a representative of the skeptical view, he was still important in Pierre Bayle's time, but was forgotten for the most part thereafter.

## LANDGREBE, LUDWIG

(1902–1992)

One of the most faithful followers of Edmund Husserl's phenomenology and phenomenological philosophy, Ludwig Landgrebe is equally known for his own contributions to these fields. What characterizes Landgrebe's work is his combination of philosophical issues and arguments with the precise delimitation of principles (or essential structures) whose rejection involves a contradiction. For example, he maintains that if one negates awareness, one nevertheless presupposes an awareness of this negation. (Landgrebe prefers the term "awareness" to "consciousness" due to the many traditional meanings associated with the latter.) As an assistant to Husserl, Landgrebe edited a number of Husserl's texts, including the classic *Experience and Judgment*. As a professor of philosophy at the university of Cologne, he formed a following of phenomenologists among whom are such notables as Klaus Held, Ulrich Klaesges, and Donn Welton. Landgrebe attracted students and audiences by his vast scholarship and personal modesty, both of which were seamlessly coupled with conceptual and logical clarity. While at home in all the modern speculative metaphysics, from Descartes through Kant, German Idealism, Nietzsche, and twentieth-century French thought, Landgrebe did not engage in speculative philosophy. When asked at DePaul University (Chicago) during a discussion of Husserl's understanding of the "subject" what its proper phenomenological status is, Landgrebe replied: "If I were to speculate, I would say that it is a monad with a window." He lectured widely in Latin America, the United States, and Eastern and Western Europe.

For Landgrebe, phenomenological philosophy is an effort to combine as clearly as possible an exposition of a given philosophical position, an analysis of the prejudgments or principles without which such a position could not be maintained, and an examination of the adequacy of the principles necessary to account for it within the

context of the phenomena encountered in human awareness. For example, Kant proposes to account for all knowledge on the basis of a priori structures in the manner of a transcendental deduction that explicates the empirical domain; but he does not, on Landgrebe's view, account for the mode of awareness required to secure access to the a priori domain at issue in this deduction. Such awareness is required, according to Landgrebe, if the a priori, or any other epistemological, ontological, or even metaphysical conditions are to be evidentially legitimated. This does not mean that Landgrebe avoids treating such conditions in terms of their conceptual meanings; however, he maintains that anyone positing such conditions will also have to show the manner in which they are accessible to awareness, because failing this, the one positing them is placed in the untenable position of positing conditions that she is unaware of. Only the interrogation of such awareness will be able to decipher what is essential in each condition. Thus Landgrebe's analyses and investigations are designed to articulate the awareness implicit in the most fundamental experiences that open up what is essential in the experienced, lived world.

### THEMES OF LANDGREBE'S WORK

Landgrebe's work has three major themes: philosophical anthropology, the basic structures of awareness, and history.

**THE FIRST THEME.** The first theme, according to Landgrebe, is called for by modern philosophical, cultural, and historical relativity. Within the latter, two claims are pre-eminent: (1) that different cultures, historical periods, and societies offer various, even clashing, interpretations of human beings; and (2) that modern scientific and technological thinking offers the means to "make" the human into something "new" or even radically different from what it has been previously. Landgrebe points out that these various views and proposed transformations of the human assume a tacit "essence" as far as awareness is concerned, which allows the difference inseparable from the different views and transformations to be directed toward something that appears to awareness as an invariant. Without the latter, no sense could be made of the claim that what "humans" are depends on cultural, historical, social, and even technical definitions and constructs. All these are different from one another. Yet simple differences would allow only the claim that at different times and in different places there were descriptively different creatures, which could only result in a catalogue of the various differing depictions. But even

those who claim that there are radical differences in cultures, societies, and histories, still insist in using the phrase “different humans”—and it is this phrase that implicates the appearance of an invariant across all differences.

**THE SECOND THEME.** Landgrebe’s second theme maintains that neither empiricism, with its emphasis on the contingency of facts, nor rationalism, with its stress on conceptuality and universal necessity, is adequate to account for concrete human awareness. The former, with its succession of impressions, cannot account for the continuity and unity of experience. The latter, as is obvious from Kant, can account for neither the unity of experience without positing the “I think” accompanying all representations, nor for the individuality wherein such representations could be attributed as “mine.” In terms of philosophical anthropology, empiricism reduces the human to a “*factum brutum*,” whereas rationalism treats the factual human as an instance of a universal concept.

Landgrebe holds that this fails to account for the distinguishability of individual subjects from one another. To confront this issue, Landgrebe’s investigation begins with the life-world and our direct experiential “opening” to it. Movement, in correlation to the things of the environment, is an epistemic requirement needed to form primal perspectivity, time awareness, and special formations. From the movement of the eyes that trace out the contours of things, to traveling around the planet, the focus and maintenance of the identity of anything is formed by body movements (kinaesthetic processes), movements that, for Landgrebe, manifest the body side of the transcendental subject. Moreover, various higher-level linguistic structures are formed at the level of movement, such as “if-then” implications: “If I want to see the other side, then I shall have to walk around the thing.” Access to time and space is equally provided by bodily activities: “If I want to see the other side, I will have to be there and then.” Activities also reveal the fundamental human “intentionality” and purposive understanding, including the instrumental selectivity of proper and unfitting factors leading to the fulfillment of purposes.

For Landgrebe, activities form habits and the primacy of the practical “I can” or “I cannot” perform something. They comprise singular “habits” (though not in the Humean sense of the association of ideas) that distinguish one individual from another. Such distinctions arise as activities oriented to common tasks wherein we begin to recognize our “otherness” on the grounds of what we can and cannot do, and not on the basis of the

initial encounter with others as subjects or minds inside of bodies. Intersubjectivity is primarily formed at the level of bodily abilities such that we recognize ourselves and others on the basis of activities. The latter, in turn, are not arbitrary, but emerge in correlation to things that make “objective” demands on such activities. This means that the world is neither in doubt nor our construct. As “Euclidean beings,” we must move around and not through things.

This claim must not be confused with any kind of realism or naturalism. According to Landgrebe, the natural presence of the world still requires an explication of the processes of awareness that are structurally distinct from the composition of things. Hence, metaphysical speculations might suggest that a special-temporal object is actually a flow of energies, or a slowly changing substance, but for awareness the thing is an X that is maintained as constant and given through the formation of movements and perspectives, of expectations of the next side and the unification of the previous side as sides of the same X. The X suggests the possibility of an indefinite ability to explore the given thing, an ability that is proper to it. One can see it from more perspectives, take it apart, and thus open up the “inner horizon” of the explored X. This complex process comprises the phenomena through which the real thing is experienced.

This level of primal awareness also opens up the “outer horizon” such that the thing is in a room, the room is in a house, the house is in the field, the field is in a region, and so on. The opening up of the external horizon is equally founded on the “I can,” which is able to go on exploring and hence comprising an open space-time horizon which, while implicit in the initial awareness of the thing, opens up possibilities for exploration of the world. One may be aware that in one’s own region there are hills, and more hills, but the horizon does not close; it is possible that beyond the hills there are deserts, lakes, flatlands, forests, cities, and strangers who “do things differently.”

This horizon extends into indefinite possibilities that the ego can concretize by going from its region to that region “then” and discovering whether its intentional orientation toward the “that and then” region, say, as a possible desert, is concretized or disappointed. The ego expected a desert and there appeared a lake. Without such a horizon of possibilities and expectations there would be no mistakes. Empiricism and rationalism fail at this juncture. It needs to be said that at the level of movement the formation of horizons belonging to awareness involves a shift from direct perceptual fulfillment to an

open world-horizon whose possibilities can only be partially concretized in direct awareness. Hence, on the one hand, in this awareness there is a “consciousness” that suggests perceptual fulfillability, whereas on the other hand, this same awareness is experienced as a transcendental condition for the experience of the world as a totality, albeit one completely accessible to a singular subject in her engagements with the world. This state of affairs leads Landgrebe to his next step: historical awareness.

**THE THIRD THEME.** Historical awareness, Landgrebe’s third theme, manifests itself as a horizon of the past achievements of others and their appropriation by the current inhabitants of the life world, including the manner that they may vary such achievements. At this level, Landgrebe raises the question concerning our experience of the historical past and rejects Hegelian dialectics, Marxian materialism, and empirical research. None can “travel to the past,” except symbolically, and none can account for such would be symbolic understanding. Apart from that, such metaphysical “accounts” of history assume a continuous theoretical time without, however, offering any justification for its continuity. In this sense, we cannot think of history as a succession of events “in time” ruled by causes, or a deduction from the “eternity” of the “laws of dialectics” (either Hegelian or Marxian). Rather, history is an active engagement of making and building, of concrete projects based on what we can do and what others have done. What they have done is present to us such that we too could have acted and performed similar tasks, but we no longer do them in this way. We have acquired different abilities and hence have no necessary continuity with our predecessors.

The discontinuity does not imply that we are not open to the understanding of how they made things, what purposes are present in their buildings, implements, and comportment. We may learn some abilities from what they did, but also vary them in order to perform our own tasks. As was the case with the horizon of awareness, history comprises a horizon of what others have accomplished, thus extending our own horizon of possibility for transforming and varying our own abilities. This means that the historical others extend my perception and abilities, thus forming a “poli-centric” field of understanding. Our own perceptions would be limited without the others from whom we “borrow” perceptions and abilities and thus recognize our limitations and possibilities—all of which, indeed, are open to the future. This view prevents speaking of a singular historical aim. Some tasks are com-

pleted and discontinued, the accomplishments abandoned; others are taken up in part after the builders and makers have long since disappeared, and still others are postponed for the future. The historical horizon of possibilities cannot be concretized in a totality; hence this openness precludes any claim that history has a singular purpose.

For Landgrebe there is another level of historical awareness: the transcendental. This type of awareness comprises a way to access the modes of perception that others assumed in their understanding of the world. Thus, whereas we may not have any knowledge of Aristotle’s psychological, social, political, and personal life, we can say, from his writings, that Aristotle regarded the world as composed of substances. Each substance could be regarded under specific categories accessible to him as well as to us. In this sense, historical awareness of others is not regarded psychologically or internally, but as a mode of awareness that comprises a transcendental orientation toward the world accessible to anyone. Even when we disagree with Aristotle or Plato, we also must be aware of the way Plato or Aristotle regarded the world. This type of awareness is already intersubjective and is a condition for the claim that our own awareness is limited and in turn extended through others. We can “borrow” Aristotle’s mode of awareness and enhance our own. This illustrates the sense in which for Landgrebe we comprise a field of poli-centric awareness that has historical depth prior to specific temporal locations. From this vantage point Landgrebe avoids various theoretical dilemmas. If a social philosophy claims that all social life, including theoretical thinking, is a result of material conditions, then previous historical views would not be accessible to us, because we do not live under those conditions. In turn, the view that all theories are based on given material conditions is itself a specific theory that reflects current material conditions; as such, it would follow that such a theory cannot make a universal claim. The same holds for theories of history that are premised on the notion that history is a contingent fact and all necessary truths, even in logic, are a result of “historical development.” A contingent fact cannot be posited as a ground of necessity, because its “sense” as such a fact excludes “necessity.”

## CONCLUSION

Finally, beyond advancing the above theoretical issues, Landgrebe also engaged in the controversies surrounding the issue of whether there is one life world that is presumed as a ground of various societies and cultures,

or whether such societies and cultures comprise distinct and, at times, incompatible life worlds. For Landgrebe this controversy reveals a most fundamental issue of awareness. If there were one life world, and we were completely immersed in it, then we would not be able to recognize our immersion in it. If there were more than one, we would then either belong to one or another and thus would interpret the other in terms of our own; hence, we would fail to recognize the distinction between them. If we can achieve access to both, then we cannot belong to either and must have an awareness of both and their differences. This awareness is taken for granted in all such comparative studies, and makes its appearance with Landgrebe's question: For whom are such life worlds given? This opens the discussion of transcendental awareness in its own right, apart from this or that (however radically different) content of such awareness. And it belongs to Landgrebe's enduring merit as a phenomenologist that this discussion can only be enriched by the consideration of his seminal researches into these three major themes of his work.

## LANGE, FRIEDRICH ALBERT

(1828–1875)

The German philosopher, historian, and sociologist Friedrich Albert Lange was born at Wald near Solingen. He studied at Duisberg, in Zürich, where he attended the lectures of a disciple of Johann Gottfried Herbart, and at Bonn. After receiving a degree at Bonn, he taught high school in Cologne, and in 1851 he became a university instructor at Bonn. His dissertation concerned the relation between theories of education and various world-views. From 1858 to 1861 he taught school in Duisberg but resigned because of a government order forbidding teachers to participate in political agitation. Lange remained in Duisberg as a newspaper editor and secretary of the chamber of commerce. His socialist sympathies were not incompatible with a genius for finance. In 1866 he returned to Switzerland and in 1870 became professor of inductive logic at Zürich. He was appointed to a professorship at Marburg in 1873 and remained there until his death. The philosophical poems of Friedrich Schiller, on which he sometimes lectured, were said to be his final comfort.

Lange's importance in philosophy rests mainly on his brilliantly written *History of Materialism and Critique of Its Present Significance* (1866). This work gave support to the opponents of materialism and helped to stimulate the revival of interest in Immanuel Kant that led to the neo-Kantian schools of the last decades of the century. Less important philosophically, but a prominent part of Lange's versatile career, was his concern with social questions, as in *Die Arbeiterfrage* (1865), and his work for constitutional reform in the direction of democratic socialism.

Lange argued that materialistic theories of reality are just as guilty of transcending the proper limits of human knowledge as are the speculative systems of idealism. He appealed to Kant's arguments, rejecting the possibility of any metaphysical knowledge that pretends to take us beyond the sphere of experience. In his view, the attempt to comprehend the world as a whole is doomed to failure. But this criticism applied as much to the materialistic rejection of unobservable spiritual or mental agencies as to their defense. According to Lange, metaphysical theories belong to the realm of art and religion, a field governed by poetizing (*dichten*). This activity is not an illegitimate one, however. It is an essential human need, expressive of men's yearnings for an ideal realm. But reli-

gion and the speculative systems of metaphysics do not yield scientific knowledge or any substitute for it.

Lange saw materialism both as a demand for mechanistic explanations of natural phenomena and as a naive realism and dogmatic metaphysics. The first demand he considered valid, but the second, he held, had been refuted by Kant and by the development of physiological psychology. The demand that natural occurrences be explained in terms of material causes is a useful, even indispensable, postulate of scientific method. In attempting to explain human behavior, for instance, it is unreasonable to think of consciousness as intervening somewhere in the series of physical events from stimulus to brain, nerve, and muscular response. Mental processes are not members of this series.

While the only valid categories for science are those that, like space, time, and causality, render nature mechanistically intelligible, these categories have no proper role beyond that of organizing our sense experience. Along with the basic concepts of physics—matter, atom, force, physical object—they are the products of human invention. The Kantian theory of the a priori had shown this, while discoveries in the physiology of sensation proved that our knowledge is sifted through human sense organs. The scientist is not a passive recipient of data; the laws that he discovers are constructions whose objectivity is only an objectivity for us. Though the world which science presents is the cognitive realm valid for all men, there is also the individual's world of ideals. To confuse the two worlds is wrong, because each has its significance.

Lange's physiological interpretation of the categories was rejected by his neo-Kantian successors at Marburg, Hermann Cohen and Paul Natorp. His influence was very strong, however, on Hans Vaihinger, whose pragmatism owes much to Lange's concept of categories as no more than maxims of scientific method. Lange's rejection of all metaphysics placed him also in the positivistic tradition, and it is no surprise that he referred to Auguste Comte as "the noble Comte." Though Lange was critical of Ludwig Feuerbach, whom he regarded as only half emancipated from G. W. F. Hegel, his own sympathetic but noncognitivist view of religion and ideals is akin to the humanism of Feuerbach.

## LANGER, SUSANNE K. (1895–1985)

Susanne Langer was an American philosopher whose work remains significant because of her distinctive views on the philosophy of art, as expressed in her books *Philosophy in a New Key* (1942) and *Feeling and Form* (1953). Though now relatively neglected, various aspects of her views remain of interest, as shown by the following considerations concerning her most characteristic doctrines.

Langer rejects positivist views of meaning and thinking according to which only literal, scientific language has any objective significance—a view the consequence of which is that any other apparent kinds of meaning are mere subjective expressions of feeling (1957, ch. 4). Instead she argues that there is another kind of objective thinking that has a different kind of symbolic form. In place of the discursive, sequential structure of linguistic statements it uses a *presentational* symbolic mode, which communicates by showing rather than saying, as do images or pictures. Such presentational modes have their origin in low-level kinds of sensory experience, which provide the basis for the often metaphorical and imagistic experiences that underlie conscious thought (1957, chs. 4, 6).

As applied to the arts, Langer claims that all of the arts are to be explained in terms of such presentational symbolic forms. For example, pictures are able to communicate their content by showing or presenting—rather than by linguistically stating—their message (1957, ch. 4); while music, dance, and other art forms similarly present rather than state their meaningful content (1957, ch. 8; 1953).

But if such presentational forms do not communicate or express objective factual information, as do discursive linguistic forms, then what do they express? Langer's answer is that they express *feeling*—not the mere subjective feelings that the positivists rejected, but instead objective forms or structures of feeling that cannot be identified either with the betrayal of the personal feelings of an artist who creates an artwork, nor with the arousal of feelings in the audience who experience that work. For example, she says of music that it “is ‘significant form,’ and its significance is that of a symbol ... which by virtue of its dynamic structure can express the forms of vital experience ... Feeling, life, motion and emotion constitute its import” (1953, p. 32). Thus artistic symbolic forms communicate, in virtue of their structure, the same forms of feeling that occur in sentient life generally.

The above views, that art involves nondiscursive symbolic forms that primarily communicate feeling, have been much criticized (e.g., see Davies 1994, ch. 3 for incisive music-related criticisms). However, there remain other, more neglected aspects of Langer's theory that are harder to dismiss, such as her view that art involves what she calls “semblance” (1953, ch. 4), a seeming or illusory quality that is both experienced as such—“The ‘otherness’ that gives even a bona fide product like a building or a vase some aura of illusion” (1953, p. 46)—and which also implies the objective unreality or virtuality of those forms themselves. This quality of semblance enables Langer to distinguish between, for instance, the *actual* spatial qualities of a sculpture or building when considered purely as a physical object, and its *seeming* spatial qualities, which in part constitute, on her view, the perceptually experienced symbolic artwork itself.

To be sure, such an account seems to imply that artworks are relative to perception in some way (Khatchadourian 1978), hence raising questions about their objective status that Langer does not answer, but many would view her general insistence on the objectivity and cultural independence of the symbolic forms of artworks as being too strong in any case. Independently of such issues of objectivity and semblance versus reality, Langer's resulting analyses are sometimes of interest in their own

right, such as her account of the ways in which sculptures are able to organize the spaces in which they occur—unlike paintings, whose spatial worlds are self-contained; this is an account that connects with other significant differences between sculptural and pictorial forms (Hopkins 2004).

In terms of the general classification of theories of art, Langer's theory is an unusual combination of a formalist and an expression theory in that her view is that all artworks express feeling in virtue of their specific symbolic form. Probably one reason for her current neglect is that she in turn neglects issues of artistic intention and individual expression that generally are thought to be at least relevant, if not central, issues in the philosophy of art. Nevertheless, whatever her theoretical flaws may be, Langer remains an engaging and insightful writer whose previous wide popularity is not hard to understand.

## LANGUAGE

What is a “language”? Is it an internal component of a speaker's mind, or is it wholly dependent on our external behavior? Is it a matter of social practice, or are languages to be viewed as independently existing abstract objects? Arguments have been offered in favor of each of these conceptions.

Adherents to these different positions can agree that linguistic theories provide the most precise way of characterizing particular languages. A theory, or grammar, supplies a set of rules describing the semantic properties of the basic expressions and their permissible syntactic combinations into meaningful wholes. The disagree-

ments that arise concern the interpretation of linguistic theories and the nature of the linguistic objects and properties they describe.

Platonists, for instance, argue that languages are purely formal, or abstract entities, whose natures are fully specified by formal theories. For the Platonist, linguistics is a branch of mathematics. In contrast, mentalists see linguistics as a branch of cognitive psychology and take linguistic theories to be about the psychological states or processes of linguistically competent speakers. For others, linguistic theories can be seen as systematizing a vast range of facts about the behavior of an individual or community of speakers, with the rules describing regularities in individual or social practice.

For Platonists, such as J. Katz and S. Soames, languages with their properties of meaning and structure exist independently of speakers. A firm distinction is drawn between languages and linguistic competence: Theories of the former are not to be confused with theories of the latter. The formal properties of a language, on which its identity depends, owes nothing to its users. Speakers of those languages may be blind to some of its properties of meaning or structure, although these may be deduced from the theory. Moreover, languages with just these formal properties exist whether anyone speaks them or not. They may be defined, according to D. Lewis, as sets of expression meaning-pairs, with the set of human (or natural) languages making up a very small portion of the set of all possible languages. The task for Platonists is to explain what makes one rather than another of these abstract entities the language of a given individual or population. To explain this the Platonist must define an *actual-language relation* between speakers, or populations, and particular abstract objects (see Schiffer for discussion). This may depend, as Lewis thinks, on facts about the conventions that exist among a population of speakers. Or it may be based upon psychological facts about speakers' competence such as the claim that speakers have internalized a grammar that somehow generates either the set, or a subset, of the sentences described by the formal theory.

Mentalists, such as Noam Chomsky and Jerry A. Fodor, insist to the contrary that the best account of speakers' actual languages should fit the facts about the meanings and structures individuals actually give to expressions: Theories of language should be tailored to the contours of linguistic competence. Thus for Chomsky, a theory of language is a theory of a speaker's knowledge of language. The formal entities described by Platonists are just projections of the linguistic properties

that speakers give to the expressions they produce and respond to. For mentalists, language is not in the world. The world contains only marks and sounds. Language is in the mind of speakers and consists in the assignments of meaning and structure given to particular marks and sounds.

For Chomsky, a grammar is a theory of the speaker's linguistic competence: An internalized system of rules or principles a person uses to map sounds to meanings. This is a body of tacit knowledge that the speaker puts to use in the production and comprehension of speech. It contains a largely innate, and species-specific, component common to all human language users. The workings of this component are described by universal grammar. Linguistic competence is just one of the factors affecting linguistic performance. Memory, attention, and other cognitive factors contribute to the actual production of speech. For Fodor, by contrast, the rules of grammar describe the actual psycholinguistic mechanisms at work in our production and comprehension of language. Language is just one of the perceptual modules, or sensory input systems, that serve our central cognitive processing.

In contrast to the Platonist and mentalist construals of language, behaviorists insist that grammars are merely theoretical representations of a speaker's practical abilities: The ability to use expressions in particular ways. For Willard Van Orman Quine, a language is a set of dispositions to verbal behavior. Quine argues that the only evidence for linguistic theory is linguistic behavior, and that many grammars will serve equally well to generate the set of sentences a speaker is disposed to produce and respond to. Thus grammars and the sentence structures they describe are construed as artifacts of theory. Chomsky denies that behavior provides the only evidence for testing theories of grammar. Psycholinguistic evidence and language acquisition are also relevant. He also argues that we could not have learned to produce and respond to so many novel sentences just on the basis of observed behavior. The data are too impoverished to support such inductive inferences: Sentences alike in surface structure differ in underlying levels of structure, and speakers respond to them differently. Chomsky concludes that speakers must bring their own internally generated representations of structure to bear on the evidence. Predictions of the sentences they find acceptable and unacceptable, and the interpretations they can and cannot allow, will be based on the fewest linguistic generalizations that fit the pattern of elicited data, and explain any gaps in the data. Claims about a speaker's grammar are thus based on inference to the best explanation about

the principles by which she generates structural descriptions (SDs) for the utterances she hears. A speaker's language is an internally generated set of structures.

Donald Davidson, like Quine, accepts that all facts about meaning must be exhibited in behavior. But unlike Quine, he holds that the assignments of meaning depend on facts about what the speaker believes and intends. Thus linguistic meaning cannot be reduced to behavior. The notions of belief and meaning are settled together by a total theory for interpreting what a speaker says and does.

Finally, is language an essentially social phenomenon? Michael Anthony Eardley Dummett argues that a language is a shared social practice upon which the possibility for communication among speakers depends. Lewis, although a Platonist, also argues that facts about the conventional regularities maintained by populations relate them to particular languages. Chomsky and Davidson, on the other hand, conclude that the fundamental notion of language is that of an individual's language, or idiolect. Differences in grammar and vocabulary between speakers ensure that no two speakers have exactly the same language: They can still communicate because there is often overlap in idiolects, and they can work out what others are saying. Chomsky distinguishes between E-languages, which are ill-assorted, externally described, and extensionally characterized social practices, and I-languages, which are the intensionally characterized, internalized grammars of individuals that assign SDs to expressions. For Chomsky, the former notion is ill-defined, so only the latter is of use in the scientific study of language. He argues that a language L cannot be identified apart from its structure, and the structure of L is the structure assigned to it by its speaker(s). He thus casts doubt on behaviorism. Many languages will share the same sounds: Whether a string of sounds is a sentence depends on how different speakers perceive those sounds. Relative to one structural assignment, the sound string may be grammatical, relative to another it may not. Quine's and Lewis's idea of a set of well-formed strings, which can be generated by different grammars, becomes problematic; instead we have a set of structures that speakers assign to sounds and signs. We might reconstruct the notion as follows: An E-language is a set of grammatical strings, where a "string" is grammatical if it has at least one structural description (SD), which is permitted by the I-language of some set of speakers in the sense that it conflicts with no principles of universal grammar (UG).

In the case of meaning, Tyler Burge has argued that word meaning depends on the social norms operating in the speaker's community; while Hilary Putnam stresses that the meaning and reference of natural terms are settled by a group of experts to whom ordinary speakers defer in their use of these terms. These social factors are compatible with the claim that the primary notion of language is that of an idiolect, as they concern vocabulary items only. Each of these different conceptions of language may coexist, all of them serving a different philosophical or scientific interest.

## LANGUAGE AND THOUGHT

Should questions about “thought”—about intentionality, beliefs, and concept possession, for example—be approached directly or, instead, indirectly via the philosophy of “language”? There are two slightly different ways in which questions about language and meaning might seem to offer illumination of issues concerning thought. One way relates to language that is explicitly about thoughts, as when someone says, “Bruce believes that boomerangs seldom come back.” The idea that a philosophical investigation of thought should proceed via a study of the logical properties of language that is about thoughts is a particular case of a more general view that philosophy of language enjoys a certain priority over metaphysics.

The other way relates to the use of language to express thoughts, and this provides the topic for the present entry. Suppose that Bruce believes that boomerangs seldom come back, and expresses this thought in the English sentence: “Boomerangs seldom come back.” Which takes priority, the meaning of the English sentence or the content of Bruce’s thought?

A claim of priority is the converse of a claim of one-way dependence: X enjoys priority over Y if Y depends on X but X does not depend on Y. Thus, a question of the relative priority of X and Y has four possible answers: X has priority; Y has priority; X and Y are mutually dependent; X and Y are independent. But the question of the relative priority of thought and language is still unclear, until the relevant kind of priority has been specified. It is useful to distinguish three kinds of priority question: ontological, epistemological, and analytical (see Avramides 1989 for a similar distinction).

To say that thought enjoys *ontological priority* over language is to say that language is ontologically dependent on thought, while thought is not so dependent on language. That is, there can be thought without language, but there cannot be language without thought. To say that

thought enjoys *epistemological priority* over language is to say that the route to knowledge about language (specifically, about linguistic meaning) goes via knowledge about thought (specifically, about the contents of thought), while knowledge about thought can be had without going via knowledge about language.

Donald Davidson denies both these priority claims. As for ontological priority, he argues (1975) that there cannot be thought without language: In order to have thoughts (specifically, beliefs), a creature must be a member of a language community, and an interpreter of the speech of others. As for epistemological priority, Davidson argues (1974) that it is not possible to find out in detail what a person believes without interpreting the person’s speech.

*Analytical priority* is priority in the order of philosophical analysis or elucidation. To say that X is analytically prior to Y is to say that key notions in the study of Y can be analyzed or elucidated in terms of key notions in the study of X, while the analysis or elucidation of the X notions does not have to advert to the Y notions. On the question of the relative analytical priority of thought and language, there are, then, four positions to consider: two priority views, and two no-priority views.

### PRIORITY FOR THOUGHT

A philosophical account of the content of thoughts—of intentionality—can be given without essential appeal to language, and the notion of linguistic meaning can then be analyzed or elucidated in terms of the thoughts that language is used to express. The analytical program of Paul Grice was aimed at an analysis of linguistic meaning in terms of the beliefs and intentions of language users, though Grice did not offer any account of the intentionality of mental states themselves (Grice 1989; see also Schiffer 1972). There are many proposals for explaining the intentionality of mental states without appeal to linguistic meaning, and these might be coupled with an elucidation of linguistic meaning in terms of mental notions. It is widely reckoned, however, that the Gricean analytical program cannot be carried through (Schiffer 1987).

### PRIORITY FOR LANGUAGE

An account of linguistic meaning can be given without bringing in the intentionality of thoughts, and what a person’s thoughts are about can then be analyzed in terms of the use of language. This view can be found in Michael Dummett’s work (1973, 1991, 1993). If a theorist attempts to give a substantive account of linguistic mean-

ing in accordance with this view, then the resources that can be invoked are seriously limited, since the account cannot presume upon everyday psychological notions such as belief and intention. Because of this, it would not be surprising to find hints of behaviorism in work that is influenced by this view.

#### NO PRIORITY—INTERDEPENDENCE

There is no way of giving an account of either intentionality or linguistic meaning without bringing in the other member of the pair. The two notions have to be explained together. This is Davidson's view (Davidson 1984). He thus maintains an ontological, epistemological, and analytical no-priority position. While the three no-priority claims go together quite naturally, it is important to note that they are separable claims and that the analytical no-priority claim is not entailed by the ontological and epistemological no-priority claims.

#### NO PRIORITY—INDEPENDENCE

The notions of intentionality for mental states and of linguistic meaning are unrelated. This view might be defended if a language is considered as an abstract entity, composed of a set of expressions together with a function that assigns a value to each expression (a proposition to each sentence, for example). On such a conception, meaning is a purely formal notion. But for the notion of linguistic meaning as it applies to a public language in use, this fourth view is implausible.

## LANGUAGE OF THOUGHT

Simply stated, the language-of-thought thesis (LOT) holds that thinking (i.e., cognition) is carried out in a languagelike medium, where the thoughts that constitute thinking are themselves sentencelike states of the thinker. Since the demise of philosophical behaviorism in the early 1960s the LOT thesis has enjoyed considerable support as a central tenet of a more encompassing representationalist theory of mind (RTM). Proponents of RTM, led by Jerry Fodor, have mounted a sustained defense of LOT.

RTM offers an account of propositional attitudes—beliefs, desires, doubts, and so on—according to which propositional attitudes relate the possessor of the attitude to a mental representation (cf. Fodor 1981). Mental representations have both semantic and physically realized formal properties: They are semantically evaluable (e.g., as being true or false, as being about or referring to certain entities or properties); they stand in inferential relations to other mental representations; and, like words, pictures, and other representations, they also have certain formal properties (e.g., shape, size, etc.) in virtue of being physical, presumably neural, entities. Mental representations, and hence propositional attitudes, have their causal roles in thinking and behavior in virtue of their formal properties. Propositional attitudes inherit semantic properties from the mental representations that are one of their relata. RTM is silent as to what kind or sort of representation these mental representations are (cf. Fodor 1987, pp. 136–138).

LOT supplements RTM with a specific proposal or hypothesis about the character of mental representations: Like sentences of a language, they are structured entities, and their structures provide the basis for the particular semantic and causal properties that propositional attitudes exhibit. More specifically, they are syntactically structured entities, composed of atomic constituents

(concepts) that refer to or denote things and properties in the world. The semantic properties of a mental representation, including both truth conditions and inferential relations, are determined by the representation's syntactic structure together with the semantic properties of its atomic constituents. Mental representations, in other words, have a combinatorial semantics. The causal properties of a representation are similarly determined by the representation's syntactic structure together with the formal properties of its atomic constituents.

Three sorts of arguments have been advanced in support of LOT. The first makes much of the apparent semantic parallels between thoughts and sentences. Both beliefs and declarative sentences, for example, are typically meaningful, truth valued, and intentional (in the sense of being about something). Both stand in various inferential relations to other beliefs and assertions. One obvious explanation of these parallels is that thought has a languagelike character, individual thoughts a sentence-like structure. A second sort of argument focuses on the productivity and systematicity of thought. Thought, like language, is productive in the sense that there are indefinitely many, indefinitely complex thoughts. Whatever can be said can also be thought. Thought, like language, is also systematic in the sense that you can think one thought (e.g., that the child bit the monkey) if and only if one can also think certain other systematically related thoughts (that the monkey bit the child). Again, one obvious explanation is that thought has a languagelike character, individual thoughts a sentencelike structure. A third sort of argument claims that much cognitive scientific theorizing seems committed to LOT. Specifically, our best theories of rational choice, perception, and learning seem committed to the claim, not simply that cognition is a matter of the creation and manipulation of mental representations, but also that these representations are sentential in character. It is claimed, for example, that our best theories of learning are a species of hypothesis testing. But such a procedure, it is argued, presupposes the existence of a language, that is, a language of thought in which the hypothesis being tested is formulated.

Proponents of LOT readily concede that these arguments are not decisive. Each is an instance of inference to the best explanation, and as such each is vulnerable to refutation by some alternative explanation that does not appeal to a language of thought.

Critics of LOT find the foregoing sorts of arguments unpersuasive for any of a number of reasons. Either they believe that there are equally good explanations that do not appeal to a language of thought, or they deny the phe-

nomena that LOT is said to explain, or they hold that the proposed explanations either rest on false presuppositions or are so sketchy and incomplete as not to merit the name, or they believe that these explanations have entailments so implausible as to impugn the explanatory premise that there exists a language of thought. Thus, for example, the argument from learning discussed above apparently entails that to learn a language one must already know a language. Many critics find in this entailment a *reductio* of LOT. Proponents such as Fodor, by contrast, have courageously embraced this entailment, arguing that all concepts, including, for example, our concept of a Boeing 747, are innate. Whatever the specific merits and defects of the arguments and counterarguments, it seems fair to say that the existence of a language of thought remains an open empirical question.

## LAO TZU

See *Laozi*

## LAOZI

(*sixth century BCE*)

Laozi, according to the *Records of History* by Sima Qian, is believed to have been an elder contemporary of Confucius (551–479 BCE) and the author of the *Laozi* (*Daode jing* or *Tao-te-ching*), a work roughly five thousand characters long. This and other traditional accounts of Laozi and the date of his work have been seriously challenged, and various hypotheses about the authorship of the work and its date have been proposed. Nevertheless, three incomplete Guodian bamboo versions of the *Laozi* excavated in 1993 prove that the text was in circulation in the fourth century BCE and may have been composed still earlier.

Laozi is believed to be the first person in Chinese intellectual history to develop a brief theory on the source and grounds of the universe, represented by the concept of Dao (also commonly called Tao in Western writings).

### DAO: SOURCE AND GROUNDS

Dao literally means "the way" and was often extended to cover the political or moral principles by which different schools expounded their ideas. Laozi attributed to this term a totally new meaning: "Dao produced the One, One produced the Two, Two produced the Three, and Three

produced the ten thousand things" (chapter 42). Here, the One, Two, and Three do not indicate anything specific, just a general cosmological formula: from Nothing to Being, one to multitude, and simple to complex. This formula has been compared to the Big Bang theory of modern astrophysics. Dao is the primordial root of all beings and creatures, and all beings and creatures in turn depend on it. As the ultimate source and grounds of the universe, Dao would be termed a metaphysical, as opposed to an empirical, concept in European philosophy. But in Chinese philosophy there is no dichotomy between the metaphysical and the physical, the ontological and the axiological, the descriptive and the prescriptive, and so on. Dao runs through the whole universe and human life; it is both transcendent and immanent. As the model for human behavior and the object of ultimate concern for human beings, Dao is similar to God, but has nothing to do with will, feelings, or purpose. Dao runs through and embodies "ten thousands things," and *de* (power or virtue) is in each being. It can be said that Dao is a quasi-metaphysical concept, and *de* is its manifestation in all beings.

### ZIRAN: THE CORE VALUE

The second key concept in Laozi's philosophy is *ziran*, or naturalness. Laozi advocates that "Man models himself on the earth, the earth models itself on heaven, heaven models itself on the Dao, and the Dao models itself on *ziran*" (chapter 25). The true meaning and message of this statement is that humans should practice the principle of naturalness, which involves allowing things to unfold without external coercion or, in the case of individual humans, without striving for things such as wealth and power. This permits actualizing natural harmony in human life and with one's surroundings. The word *ziran* comprises two parts: self (*zi*) and so (*ran*). Its basic meaning is "self-so." It may be rendered as naturalness to show its adjectival meaning and grammatical function as a noun.

One should not confuse *ziran* with Nature or the natural world. *Ziran* is used to indicate Nature in modern Chinese, but in classical contexts words such as *tian* (heaven), *di* (earth), and *wanwu* (ten thousand things) denoted the natural world. Some scholars relate *ziran* with Thomas Hobbes's (1588–1679) "state of nature," which is a hypothetical term for scientific argument and suggests that everyone is at war with everyone. Instead, Laozi's *ziran* is the ideal condition of human societies, namely natural harmony, and represents the highest principle and core value in his philosophy; it is embodied and

promoted by Dao. Natural harmony and order are valuable and desirable compared with humanly contrived order, which depresses human nature and arouses resistance and even inevitably leads to chaos. Human nature can only flourish within societies that have natural order, hence *ziran* is also the optimal condition of individuals. Laozi contends that “the sage should foster the *ziran* of the ten thousand things and dare not take action” (chapter 64). This leads us to the next fundamental concept: *wuwei*.

### WUWEI: PRINCIPLED METHOD

*Wuwei* also comprises two parts: no (*wu*) and action (*wei*). Superficially, it means “no action at all,” but in fact *wuwei* only negates some kinds of actions, not all. Obviously, “fostering the *ziran* of ten thousand things” is not the kind of action *wuwei* would exclude. The agent of *wuwei* in Laozi’s theory is mainly the sage, the ideal model of rulers, who fosters potential in others instead of directly ordering, forcing, interfering, and interrupting. So there is a social and political message in Laozi that is absent in the Inner Chapters of the *Zhuangzi*. Laozi’s *wuwei* implies two aspects: Its negative expression suggests preventing certain societal actions, such as oppression, confrontation, and strife, while its positive meaning advocates an alternative, sophisticated manner of behavior for better results of natural development and harmony in societies, such as fostering, assisting, and being patient. In his famous proclamation about “doing nothing yet leaving nothing undone,” Laozi clearly reveals the positive objective of *wuwei*. “Doing nothing” is a means of realizing the end of “leaving nothing undone.” *Wuwei* actually purports to be both a superior approach to and the consummate realization of human activity. It derives from comprehensive humanistic perspectives and considerations, not from fashions or trends of governance aimed at achieving immediate benefits.

Humans make two kinds of mistakes: One is not making enough effort, the other is overdoing. The former mistake is easy to remedy because it does not waste too many resources or shake morale. Correcting the second is more difficult, as in the case of environmental degradation. Here is an additional sense in which *wuwei* is reasonable and significant.

### REVERSION: PARADOXICAL THINKING

Another distinctive feature of Laozi’s philosophy is his dialectical or paradoxical thinking, which emerges through doctrines dealing with the unity and transfor-

mation of pairs of contradictions. One doctrine concerns the interdependence of opposite things and concepts. For example, “Calamity is that upon which happiness depends; happiness is that in which calamity is latent.” Another is the reversibility of opposite sides, such as the “correct can become the perverse, and good may become evil.” According to Laozi, all things are in motion and they are changing and proceeding toward their reverse. Thus, humility produces greatness, and ambitions bring about failure. Obverse and reverse sides often exchange positions. Things in both human societies and the natural world can work out to be the very opposite of our expectation and intention.

To sum up, *wuwei* is the methodological principle for fostering *ziran*, the core value in Laozi’s system. Dao, as the ultimate source and grounds of the universe, is the quasi-metaphysical and axiological foundation for both *wuwei* and *ziran*, while the theory of dialectics supports *ziran* and *wuwei* from the perspective of human experience.

## LA PEYRÈRE, ISAAC (1596–1676)

Isaac La Peyrère, or Pereira, was born in Bordeaux, France, a Calvinist of Portuguese New Christian, or converted Jewish, background. He became the Prince of Condé's secretary. Apparently he was friendly with leading Parisian avant-garde intellectuals such as Pierre Gassendi, François de La Mothe Le Vayer, Hugo Grotius, Guy Patin (1601–1672), and Ménage. La Peyrère's first book, *Du rappel des juifs* (1643), deals with the conversion of the Jews, their potential return to Palestine, and the beginning of the Messianic Age. In 1644 he went to Denmark and gathered there the material for his *Relation de l'Islande* (1663) and *Relation du Groenland* (1647), both written as letters to La Mothe Le Vayer. His most famous works, the *Prae-Adamitae* and the *Systema Theologicum ex Prae-Adamitarum Hypothesi*, apparently written by 1643, were published in Amsterdam in 1655. Queen Christina of Sweden (1626–1689), whom he had recently met in Belgium, offered to pay the publishing expenses, so he took his manuscript to Amsterdam to get a printer. Five editions of these works were published almost immediately, and the book appeared not only in Latin but in English and Dutch. Among the early readers of his book was the young Spinoza. La Peyrère argued that the only consistent interpretation of certain biblical passages, and of the anthropological and historical evidence about the Chinese, Mexicans, Eskimos, and other peoples, is that there were men before Adam and that the Bible deals only with Jewish history and not world history. The effect of this work was like that of a bombshell to the seventeenth-century intellectual world. It appeared at almost the same time as Archbishop James Ussher's (1581–1656) proof, on the basis of biblical data, that the world was created in 4004 BCE. La Peyrère was immediately attacked and refuted on all sides. His book was burned in Paris, and he himself was arrested and kept in prison in Belgium for six months until he retracted his views and became a Catholic. He then went to Rome and begged the pope's forgiveness, publishing a formal retraction of his views. In 1659 he entered a religious order near Paris, where he remained until his death. Despite his official retractions, it is believed that he continued to hold to his pre-Adamite views. For example, Pierre Bayle cites a

letter in which La Peyrère's religious superior is supposed to have said that "he was always writing books that ... would be burned as soon as the good man died. La Peyrère was the best man in the world, the sweetest, who tranquilly believed very little."

La Peyrère's revolutionary work on the pre-Adamite theory had tremendous influence on seventeenth- and eighteenth-century thought. In raising the possibility that biblical data might only apply to Jewish history, he introduced a radical new conception of human development and led people to speculate on the relative merits of various cultures and religions. Further anthropological and geological studies, as well as investigations into comparative religion, soon led to the abandonment of biblical chronology and history as the framework for understanding all human history and led also to the beginning of higher criticism of the Bible by writers like Spinoza and Richard Simon and to the Enlightenment critiques of traditional religion. Pre-Adamism was a radical hypothesis in the Enlightenment that accounted for the variety of human beings.

Most writers for at least a century after La Peyrère seem to have been directly or indirectly aware of his pre-Adamite hypothesis and its extraordinary implications. In the nineteenth century La Peyrère's pre-Adamite hypothesis was developed into a racist view and finally into the ideology of British Israelites and of the Aryan Nation in the United States.

## LAPLACE, PIERRE SIMON DE

(1749–1827)

Pierre Simon de Laplace, the French astronomer and mathematician famous for his celestial mechanics and theory of probability, was born in Normandy. Upon coming to Paris, he attracted the attention of Jean Le Rond d'Alembert, who found him employment in the *École Militaire*. Here he taught mathematics to trainee artillery officers, among whom was Napoleon Bonaparte. When the revolutionary government established the *École Polytechnique*, Laplace was one of its founding professors. He served with distinction on many of the great committees of the French Academy of Sciences and of the government. He helped devise the meter, standardized weights and measures, and worked out an ingenious system of sampling to provide an economical and efficient census. The elegance of his mathematical work has yet to be rivaled, and his power of analysis is matched only by that of Isaac Newton and Joseph-Louis Lagrange. His philosophical opinions, especially those in his *Exposition du système du monde* (*The System of the World*) and *Essai philosophique sur les probabilités* (*A Philosophical Essay on Probabilities*), have a bluntness and clarity of expression that ensured their popularity.

Laplace's adult life was passed in conditions of civil strife and sometimes of chaos, but despite his revolutionary affiliations, the restoration of the Bourbons brought him neither poverty nor disgrace; he died honored by all, a newly created marquis. Against this background of political confusion, he came to believe that the theory of probability, properly and widely applied, would reduce most of the problems of society (like the attainment of justice) to something manageable; with the help of probability theory, he believed, a man of delicate intuition and wide experience could find practical solutions to most social difficulties.

Laplace's scientific work had a strong element of tidiness about it. It consisted largely of the final polishing of the Newtonian enterprise, knitting up its loose ends. Using the improved calculus devised by his colleagues, particularly Lagrange, he removed all known errors from,

and explained all known anomalies in, the Newtonian cosmology and physics. It seemed to Laplace that there was no phenomenon that the improved and polished Newtonian physics was incapable of handling. He came to regard the enormous explanatory power of the system as practically a demonstration of its truth. New observations would only confirm it further, he thought, and their consequences were as certain as if they had already been observed.

What had produced this remarkable confidence was a series of complete successes. Newton had never been convinced of the stability of the solar system, which he suggested might need divine correction from time to time. Laplace showed, in effect, that every known secular variation, such as the changing speeds of Saturn and Jupiter, was cyclic and that the system was indeed entirely stable and required no divine maintenance. (It was this triumph that occasioned his celebrated reply to Napoleon's query about the absence of God from the theory; Laplace said that he had no need of that hypothesis.) He also completed the theory of the tides and solved another of Newton's famous problems, the deduction from first principles of the velocity of sound in air. Laplace added a very accurately estimated correction for the heating effect produced by rapidity of the oscillation, which was too short to allow the heat of compression to be dissipated.

### DETERMINISM AND PROBABILITY

Not only was Laplace confident of the Newtonian theory, but he was also greatly struck by its determinist nature. Where one could gather accurate information about initial conditions, later states of a mechanical system could be deduced with both precision and certainty. The only obstacle to complete knowledge of the world was ignorance of initial conditions. Laplace's confidence in Newtonian theory is exemplified in the introduction to his *Philosophical Essay on Probabilities*, in which he envisaged a superhuman intelligence capable of grasping both the position at any time of every particle in the universe and all the forces acting upon it. For such an intelligence "nothing would be uncertain and the future, as the past, would be present to its eyes. The human mind offers, in the perfection which it has been able to give to astronomy, a feeble idea of this intelligence" (*Philosophical Essay*, p. 4).

But this ideal is difficult to attain, since we are frequently ignorant of initial conditions. The way to cope with the actual world, Laplace thought, is to use the theory of probability. The superhuman intelligence would

have no need of a theory of probability. Laplace would have regarded as ridiculous the idea that there could be systems that would react to stimuli in only more or less probable ways. He said, “The curve described by a simple molecule of air or vapor is regulated in a manner just as certain as the planetary orbits; the only difference between them is that which comes from our ignorance” (*Philosophical Essay*, p. 6). He then defined a measure of probability as follows:

The theory of chance consists in reducing all the events of the same kind to a certain number of cases equally possible ... and in determining the number of cases favorable to the event whose probability is sought. The ratio of this number to that of all the cases possible is the measure of this probability, which is thus simply a fraction whose numerator is the number of favorable cases and whose denominator is the number of all the cases possible. (*Philosophical Essay*, p. 6)

This is the definition of probability known today as the proportion of alternatives. Then as now, it involves the very tricky notion of equipossible cases. Laplace deals with this notion by glossing equipossible cases as those that “we may be equally undecided about in regard to their existence” (*Philosophical Essay*, p. 6).

This account does have its difficulties. Equal indecision is not at all easy to determine and may, in the end, hinge upon states of mind quite irrelevant to a sound estimate of probabilities. Throughout his study of probability Laplace refers to such subjective factors as honesty, good judgment, and absence of prejudice, which are required in using probability theory. However, he does give a much sounder criterion for its practice; it encourages one to reckon as equally possible those kinds of events instances of which we have no special reason to believe will occur. Equality of ignorance then becomes his criterion for equality of possibility. Laplace is quite happy about this, since he believed—perhaps rightly—that the proper occasion for the recourse to probability is ignorance of the initial conditions, the relevant theory, or both. Actual estimates of probability are made statistically. In his practical examples he appears to depend on a further distinction, which also seems correct. It is the distinction between the meaning of the statement of probability for a certain kind of event (that is, ratio of number of favorable to equipossible kinds of events) and the usual estimate of this probability, which is the relative frequency of actual events of the kind under consideration among all appropriate cases.

## APPLICATIONS OF PROBABILITY

Laplace made several practical applications of probability theory. In science he applied it to the problem of sampling for the census and to the theory of errors; to both of these studies he made valuable contributions. He also believed that probability theory would have great utility in the moral sciences. He studied the optimum size for a jury to give the least doubtful verdict and the voting procedures of assemblies both on candidates for office and on propositions. He discussed the advantages and disadvantages of voting by ranking in order of merit and of voting by the knockout majority system. In this study and in his reflections on what it is reasonable to risk and in what kind of game, one gets the occasional glimpse of Laplace’s basic moral principle, “Only bet on a reasonably sure thing.”

## PHILOSOPHY OF SCIENCE

In his philosophy of science and in his views on the nature of scientific method, Laplace expressed himself somewhat along the same lines as Newton, but more liberally. He saw quite clearly that science is not the accumulation of isolated and particular items of information. “It is by comparing phenomena together, and by endeavouring to trace their connection with each other, that he [man] has succeeded in discovering these laws, the existence of which may be perceived even in the most complicated of their effects” (*System*, Vol. I, p. 205). In searching for connections we do not need to shun hypotheses. Laplace said of hypotheses what Newton should have said, considering the use he made of them: that if we refuse to attribute them to reality and regard them merely as the means of connecting phenomena in order to discover the laws (which we correct according to further observations), they can lead us to the real causes or at least enable us to infer from observed phenomena those which given conditions ought to produce.

In fact, it is by excluding on the basis of decisive experiments all those hypotheses that are false that “we should arrive ... at the true one.” Ideally, Laplace sees scientific method as the formulation of generalizations of connection between phenomena, proceeding inductively from phenomena to laws (which are the ratios connecting particular phenomena), and from these to forces. When these forces reveal some general principle, that principle is verified by direct experience, if possible, or by examination of its agreement or disagreement with known phenomena.

Testing consists both of trying to formulate a deductive system based upon the highest hypotheses and

designed to explain the phenomena, “even in their smallest details,” and of seeing whether the theory agrees with as varied and as numerous phenomena as are relevant to it. If a theory passes these tests, it “acquires the highest degree of certainty and of perfection that it is able to obtain.”

Laplace saw that our confidence in predictions had to be based upon confidence in some principle of the uniformity of nature. The sources of his confidence in some principle of uniformity were twofold. First, there is the condition of the absence of interference. If there is no reason why a change should occur, a change will not occur—a principle deeply embedded in Newtonian science. As Laplace put it, “Being assured that nothing will interfere between these causes and their effects, we venture to extend our views into futurity, and contemplate the series of events which time alone can develop” (*System*, Vol. I, p. 206). Second, simplicity was to be regarded as a mark of future reliability. The principle of induction, said Laplace, is that “the simplest ratios are the most common.” He said, too, “We judge by induction that if various events, movements for example, appear constantly and have been long connected by a simple ratio, they will continue to be subjected to it” (*Philosophical Essay*, p. 178). The theory of probability supplies a connection between the two sources of confidence, for, said Laplace, we conclude from the fact that a simple ratio is found among quantities in nature “that the ratio is due, not to hazard, but to a regular cause.” Thus, if no other causes intervene, we may expect a likeness of effects, in fact, a uniformity of nature.

Summing up scientific method, Laplace said, “Induction, analogy, hypotheses founded upon facts and rectified continually by new observations, a happy tact given by nature and strengthened by numerous comparisons of its indications with experience, such are the principal means for arriving at truth” (*Philosophical Essay*, p. 176).

## LAPSHIN, IVAN IVANOVICH (1870–1952)

Ivan Ivanovich Lapshin, the Russian neo-Kantian philosopher, was born in Moscow and studied at the University of St. Petersburg under the leading Russian neo-Kantian, Aleksandr Vvedenskii. Lapshin pursued his studies abroad for some years after 1893, concentrating particularly on Kantianism in English philosophy. With the publication in 1906 of his dissertation and chief philosophical work, *Zakony myshleniia i formy poznaniia* (The laws of thought and the forms of cognition), he received his doctorate from the University of St. Petersburg and in 1913 was made professor of philosophy at that institution. Along with many other noted Russian scholars Lapshin was exiled from the Soviet Union in 1922; he settled in Prague, where he lived until his death. His many writings cover a broad range of topics in philosophy, psychology, literature, music, and art, and include Russian translations of works by William James.

In his chief work Lapshin developed an antimetaphysical position on Kantian grounds, arguing specifically that the “laws of thought” derive their necessity solely from their connection with the forms through which sensory objects are cognized and that, therefore, it cannot be known whether these laws apply beyond the bounds of possible experience. According to Lapshin the law of contradiction, for example, can be understood only in reference to space and time (which, contrary to Immanuel Kant, he held to be categories of the understanding rather than forms of sensibility); and since the categories of space and time do not necessarily apply to transemperical objects, neither does the law of contradic-

tion. Consequently nothing can legitimately be affirmed of “things in themselves,” not even their existence.

Lapshin devoted little attention to problems of ethics and did not accept Kant’s transition to a noumenal realm and to religious faith via the dictates of moral consciousness. In general he regarded metaphysics and religion as entirely without epistemological foundation and as obstacles to the progress and vitality of human thought.

Much of Lapshin’s later philosophical work was concerned with questions of the psychology of creativity and with the epistemological basis of our knowledge of other minds. His two-volume study of creativity in philosophy (1922) was complemented by a number of other writings on creativity in literature and the arts.

As early as 1910 Lapshin had published a historical account of the problem of other selves, and in 1923 he presented his resolution of the problem in the article *Oproverzhenie solipsizma* (A refutation of solipsism). He argued that our sense of the immediate givenness of other selves is an illusion based on the projection of subjective impressions; other selves are hypothetical constructs, which can be called “immanently real” but cannot be shown to have transcendent reality.

## LA ROCHEFOUCAULD, DUC FRANÇOIS DE (1613–1680)

Duc François de La Rochefoucauld, the French epigrammatist and moral critic, was born in Paris; he was known as the prince de Marcillac until he succeeded his father in 1650. An incurable love of adventure and imprudent women brought him into early conflict with Cardinal Richelieu, who imprisoned him briefly in the Bastille in 1637. Contempt for Jules Mazarin, whose treatment he bitterly resented, led La Rochefoucauld to join the faction of the Cardinal de Retz when the Fronde broke out in 1648, but before the end of hostilities he had gone over to Condé’s side and was seriously wounded in 1652.

In 1656 he was permitted to return from exile to Paris, where he lived until his death, which occurred after many crippling years of gout. During this period, he became a leading figure in salon society, where his closest friends were Mme. de Lafayette and Mme. de Sévigné, as well as in the Port Royal circle, which included Antoine Arnauld and Mme. de Sablé.

Shortly after his return to Paris he began his *Mémoires*, first Books III–VI (covering the Fronde), then Book II (on the years from 1642 to 1649), and finally Book I (on the years from 1624 to 1642). A grossly inaccurate pirated Dutch edition, which appeared in 1662, caused a great scandal, but the authentic text was not published until the nineteenth century. These *Mémoires*, although less ample and distinguished than those by Retz on the same events, are indispensable to an understanding of the *Maximes*, since they show the inconsistency, dishonesty, and superficiality characteristic of the aristocratic *Frondeurs*.

The *Maximes* were begun as a joint enterprise with Mme. de Sablé and Jacques Esprit (of the Port Royal Circle) and reflect a popular salon pastime, but after the appearance of a pirated Dutch edition in 1664, successive authorized editions followed from 1665 to 1678, considerably altering the scope and nature of the work. The contributions of La Rochefoucauld’s friends, as well as maxims too closely resembling such models as Seneca and Montaigne, were deleted, and the original brief moral reflections that occupied a page or so were cut up into the present highly condensed epigrammatic form of a few lines.

The *Maximes* deal with human nature from a strictly human standpoint, all references to God and religion having been systematically removed. They give a lucid

and penetrating analysis of the manifold forms taken by self-interest, which, according to La Rochefoucauld, is the fundamental motive behind human behavior. He also claims that “reason is most often the dupe of the heart,” so that human nature is a mass of capricious and unpredictable passions of physiological origin, and what commonly passes for virtue, when it is not pure accident, is really disguised, or unrecognized, vice. He shows little confidence in the Cartesian program of passions controlled by reason and will, and no confidence whatsoever in any concept of natural virtue such as that held by admirers of the virtuous pagans of antiquity. The *Maximes* stress the importance of self-analysis and being honest with oneself; without these qualities love and friendship are a hollow sham, and even with them they may be no more than exercises in egoism.

The predominantly pessimistic outlook reflected in the *Maximes* is partly relieved by the brilliance of the style and the subtlety of the analysis, and also partly by various qualified admissions that true friendship and genuine integrity (*honnêteté*), although rare, may occasionally be encountered. The growing pressure of conformism in a highly artificial society, the author’s own experience of pointless heroism and shabby motives in the *Fronde*, and above all his proud and melancholy temperament serve to explain the harsh verdict of the *Maximes*. For all their abiding interest these epigrams remain the direct product and reflection of the age in which they were written. Some brief essays, portraits, and numerous letters constitute the rest of La Rochefoucauld’s work.

## LAROMIGUIÈRE, PIERRE (1756–1837)

Pierre Laromiguière, the French professor of philosophy, was born at Livignac in the district of Rouergue. As a young man, he was ordained a priest and exercised his ecclesiastical duties for a short period before becoming professor of philosophy successively at Carcassonne, Tarbes, Toulouse, and the Sorbonne. He was a close student of Étienne Bonnot de Condillac and an associate of the Idéologues but departed from the teachings of both in certain particulars. Excessively shy, he refused to propose his candidacy to the French Academy, though twice urged to do so, and confined his public appearances to the classroom. He died in Paris, one of the most esteemed and beloved of teachers. Among his more famous pupils were Victor Cousin and Théodore Jouffroy.

Laromiguière’s disagreement with the school of Condillac arose over the question of the mind’s passivity. He argued that if all our ideas were modifications of sensory material impressed upon us by external causes, it would be impossible to account for attention, comparison, and reason. These, he held, were essentially active. There is a fundamental distinction to be made, he said, between seeing and looking, listening and hearing, and the difference cannot be explained if the soul is a passive recipient of sensory stimuli. Activity was indefinable for Laromiguière, since it had no anterior ideas from which it could be derived. He seemed to believe that anyone hearing the term would grasp its meaning.

The three activities of the understanding were attention, comparison, and reasoning; and the three activities of the will corresponding to them were desire, preference, and freedom—the latter being the power to act or not to act. Laromiguière’s insistence on the soul’s activity was most welcome to his contemporaries, for it restored to men the autonomy that, they felt, Condillac had destroyed. While disagreeing with Condillac on this point, Laromiguière agreed with his predecessor that the primary business of philosophy was the analysis of ideas. In his best known and extremely popular work, *Leçons de philosophie*, which ran through six editions between 1815

and 1844, he assigned to metaphysics the single task of discovering the origin of all our ideas.

Laromiguière was particularly admired for the perfection of his literary style, the fame of which was acknowledged even by Hippolyte-Adolphe Taine.

## LAROUÏ, ABDULLAH

(1935–)

A Moroccan intellectual born in 1935, Abdullah Laroui taught at Mohammed V University in Rabat and was one of a distinguished group of Moroccan thinkers such as M. A. Lahbabi and M. A. al-Jabri. His work involves a variety of theoretical and disciplinary perspectives, including history (his main professional discipline), sociology, philosophy, and literature. He has produced histories of the Maghreb (North Africa) and of the Arab world in general, and his writings on modernity and strike at the heart of many key issues that are important for Arab culture in the postcolonial world. He raised in particular the questions how history should be written and how to understand the cultural life of a group of people through understanding their history. This comes out as a much more complicated issue than might initially appear to be the case, and Laroui uses the conceptual machinery of both Ibn Khaldun and Machiavelli to try to position Arabi history within an appropriate theoretical context.

One of Laroui's major achievement is in laying out the ambiguous nature of some of the key concepts of Arab culture in the contemporary world, including modernity, the state, authenticity, continuity, rationality, and tradition. He argues that the Arab world cannot adopt wholeheartedly the Western concept of the state since this is essentially a secular notion and pays little regard to the past, while for Arabs the link with Islam and their history is a crucial aspect of political legitimacy. In any case, the state is only a part of the whole Islamic *umma*, or community, and there is a notion of an Arab *umma* in which the state exists, and that produces a nexus of relationships for the concept of the state, that makes little sense of the Western notion. As with his predecessor Ibn Khaldun, Laroui has an approach to understanding society that makes it important to develop and clearly specify a theoretical perspective and put a particular social structure with in its historical and cultural context. In this way it is possible to say something both true and interesting about Arab ideology, while using the conceptual tools imported directly from outside the region is unlikely to be helpful.

Laroui's thought has moved from his earlier Marxism to produce a more nuanced approach to the philosophy of history and the understanding of culture. He is part of a significant movement in the modern Arab world that tries to define Arab culture and its unique features, while at the same time making use of theories from outside the region where they can shed light on the issue.

## LASSALLE, FERDINAND

(1825–1864)

Ferdinand Lassalle, the German socialist, was born Ferdinand Lasal in Breslau, Silesia, of a middle-class Jewish family. The young Lassalle—he gallicized his name—was a poor and rebellious student. Quite early he indicated his persistent, but never conflicting, longings both to relieve the oppressed and to achieve aristocratic status. These

two desires illuminate the paradoxical nature of a man who championed the causes of oppressed workers and oppressed noblewomen with equal vigor. He corresponded regularly with Karl Marx, defended the honor of the Countess von Hatzfeldt in a lengthy and celebrated lawsuit, sought the acclaim of Berlin society, founded the Allgemeiner Deutscher Arbeiterverein (the first political party for German workers), dressed fastidiously, and died at the age of thirty-nine, from wounds suffered in a duel with Count von Racowitza.

Lassalle attended the universities of Berlin and Breslau, falling under the influence of Hegelian philosophy at the latter. But, although he had philosophic pretensions and sought the acclaim of philosophers, he preferred a life of action to one of theory; and his fame rests chiefly on his founding the Allgemeiner Deutscher Arbeiterverein in 1863, to which German Social Democrats still trace their origin.

Lassalle referred to his exposure to G. W. F. Hegel as his “second birth.” He avidly consumed Hegel’s works, as well as those of young Hegelians like David Friedrich Strauss and Ludwig Feuerbach. Hegel’s reference to the ancient Ionian philosopher Heraclitus of Ephesus as his forerunner led Lassalle to study Heraclitus; and he sought to demonstrate that Heraclitus had forecast Hegelian ideas. Lassalle also aspired unashamedly to the fame that a major philological and philosophical work would provide for him in German society. He began his research while not yet twenty, but did not complete it until fifteen years later. Berlin academicians hailed the publication in 1858 of *Die Philosophie Herakleitos des Dunkeln von Ephesos*, but later critics have found grave defects in the work, most notably Lassalle’s preoccupation with Hegel rather than Heraclitus.

Hegelian ideas dominated Lassalle’s historical and economic thought as well. His historical and economic theories, although not carefully formulated, emerge most clearly from the works of his last years, when he was organizing the Arbeiterverein, especially *Das System der erworbenen Rechte* (Leipzig, 1861); *Arbeiter-Programm* (Berlin, 1862); *Über Verfassungswesen*; *Die indirekte Steuer und die Lage der arbeitende Klassen* (1863; reprinted Berlin, 1874); and *Herr Bastiat-Schulze von Delitzsch, der ökonomische Julian, oder Kapital und Arbeit* (Berlin, 1864). He shared with Marx the belief that revolutions are not “created” by revolutionaries, but occur as the result of a historical process. Men called revolutionaries are in fact merely the midwives to a new age produced in the womb of time. Lassalle described this process in Hegelian terms. A new social order, when it appeared,

would rise on the wings of Hegelian ideas. The bourgeois idea of freedom had destroyed feudal solidarity in 1789. The bourgeoisie had liberated itself by reducing the state to the role of “nightwatchman.” The proletariat would in turn liberate itself through association, at first within a political party that would demand and obtain universal suffrage from the state. Having achieved universal suffrage, the proletariat would use the power of the state to form great workers’ associations or cooperatives. These would in turn liberate the worker from the cruel “iron law of wages” and achieve freedom for him.

Lassalle worked arduously at organizing the workers into a national political party. He did not intend to overthrow the state, but to use it. The idea of freedom would find eventual embodiment through the state. All previous conflicts would be synthesized in this final stage of history. Thus Lassalle accepted the Prussian state and perhaps even the Prussian monarchy. His position on the latter, as well as on private property, is ambiguous. Lassalle wrote and agitated under Prussian censorship and was constantly being tried for treasonable activity. His published works and public statements are therefore not always consistent with his private correspondence and conversations.

Lassalle’s relationship with Marx waxed warm and cool. Lassalle undoubtedly admired Marx and sought the latter’s approval, whereas Marx disapproved of much that Lassalle wrote and did. Marx regarded Lassalle as a friend, an informant, a creditor, a publishing agent, and an immature, pompous plagiarist. They broke off their correspondence before Lassalle’s death.

## LATIN AMERICAN PHILOSOPHY

Latin American philosophy covers primarily the philosophy produced in the parts of the Americas that belonged to the Spanish and Portuguese empires after 1492. The Maya, Toltec, Aztec, and Inca civilizations engaged in some philosophical speculation in the form of religious myths and cosmological accounts prior to the arrival of the Europeans, but most of the records of these efforts were destroyed during the conquest. As happened with almost everything else in the wake of colonization, Iberians took control over the development of philosophy and scholastic philosophy became the most influential philosophical trend in the New World.

The encounter posed new challenges to European thought and initiated new developments in both Europe and Latin America. In Iberia, new issues, primarily concerned with the rights of conquered peoples and just war, took center stage, and the greatest Iberian philosophers of the times, Francisco de Vitoria (c. 1492–1546) and Francisco Suárez (1548–1617) addressed them. In the colonies, some attention was given to pre-Columbian worldviews, but these slowly receded into the background, making way for the concerns, first, of the Iberians living in the colonies and, then, of *criollos*—that is, native-born authors.

The colonial roots of Latin American philosophy helped set the stage for the emphasis on sociopolitical issues, such as human rights and social justice, which have been so central to the philosophical development in the region. In addition to addressing standard philosophical questions concerning the nature of being, knowledge,

and value, Latin American philosophers have demonstrated a strong commitment to more concrete issues involving educational policy, political organization, and social reform. In contrast to their Anglo-American colleagues, many Latin American philosophers have developed their ideas not in technical articles and systematic treatises intended for specialized audiences, but in newspaper articles, essays, and even fiction, meant to be read by a broad public. This is consonant with the view that philosophy should be a tool for social change and has led some historians to speak of two trends in Latin American philosophy: academic and Latin Americanist. The first is inspired by European philosophy and is practiced in universities; the second is more autochthonous and extends beyond the boundaries of academia. Most authors cited in this entry belong to the first trend. Some of the best known thinkers who belong to the second are Eugenio María Hostos (Puerto Rico, 1839–1903), Justo Sierra (Mexico, 1848–1912), José Martí (Cuba, 1853–1895), José Enrique Rodó (Uruguay, 1871–1917), Jorge Luis Borges (Argentina, 1899–1986), Octavio Paz (Mexico, 1914–1998), Carlos Fuentes (Mexico, b. 1928), Mario Vargas Llosa (Peru, b. 1936), and Luis Castro Leiva (Venezuela, 1943–1999).

### MAJOR PERIODS OF LATIN AMERICAN PHILOSOPHY

Four major periods in the history of Latin American philosophy stand out: colonial, independentist, positivist, and contemporary.

#### COLONIAL PERIOD (C. 1550–1750)

Latin American philosophy begins within the scholastic fold provided by the Iberian clergy sent by the Spanish and Portuguese Crowns to convert the indigenous inhabitants of the territories they had conquered. The main philosophical centers during the early colonial period were Mexico and Peru, the two places in which major empires had flourished and the Europeans found the gold and silver they coveted. The texts studied were those of medieval scholastics and of their Iberian commentators, and the issues addressed concerned logic, natural philosophy (physics), and metaphysics. The first author to publish systematic treatises on these topics was Alonso de la Vera Cruz (1504–1584), but it was Antonio Rubio's (1548–1615) *Logica mexicana (Mexican Logic, 1603)* that first gained prominence in the New World and Europe.

Although scholasticism was central to, and many thinkers continued to write within, this tradition, others were guided by humanist ideas. In particular, they were

concerned with the political and legal questions raised by the process of colonization. Arguably, the most important of these thinkers was Bartolomé de las Casas (1474–1566), a Dominican friar from Spain who became the leading champion of the rights of the Indians. His long life was devoted to arguing before the Spanish Crown that the indigenous groups of New Spain were not barbarians “in the strict sense”; they were no less human than Spaniards and so just as deserving of the same basic human rights.

Las Casas first brought up what became known in Spain as “the Indian Question.” As early as 1515, he began to petition the Crown to enact laws that would eliminate the notorious *encomiendas*. This system gave Spanish settlers custody of groups of indigenous peoples who were then exploited in mining and agriculture. In 1550 an important debate took place in Valladolid, Spain, between the humanist Juan Ginés de Sepúlveda (1490–1573), a leading ideologue of the *Conquista*, and Las Casas. Las Casas argued that it was unjust to wage war against the indigenous peoples and to enslave them.

Las Casas’s defense of the Indians reflects the influence of several sources. The thought of Aristotle (384–322 BCE), known as “the Philosopher” among scholastics, is behind several distinctions upon which Las Casas based his defense. Other sources included canon and Roman law, and such Christian thinkers as Augustine (354–430) and Thomas Aquinas (c. 1225–1274). Las Casas was scholastically trained and the scholastic method informs the structure and content of his rebuttal of Sepúlveda.

The debate between Las Casas and Sepúlveda raised questions concerning the natures of humanity and justice, issues that continue to shape Latin American philosophy to this day. Social injustice did not have only one face. Women also suffered oppression, although for most of the thinkers of the colonial period, this went unnoticed. Aristotle had claimed that women were inferior to men, and most of his scholastic followers did not question this view. But there were isolated voices that cried out against the claim that women were not fit for intellectual activity. One of the most eloquent and powerful of these voices was that of the nun Sor Juana Inés de la Cruz (Mexico, 1651–1695). A recurring theme in her writings is the image of a human being as a microcosm, and reflects the influence of neoplatonic philosophy upon her thought. Much of her writings, whether in prose or poetic form, displays a concern with the unjust position of women in colonial society.

## INDEPENDENTIST PERIOD

(C. 1750–1850)

A more complete break with scholasticism was attempted during the independentist period. This phase of Latin American thought receives its name from the political rationale articulated in the eighteenth century to gain independence from Spain and Portugal. The intellectuals engaged in this enterprise were men of action who used ideas for practical ends. The strong influence of Utilitarianism is reflected in their emphasis on progress and the attempt to employ ideas as tools for social change. Another source that shaped the period came from the liberal views of the French *philosophes*, who made reason a measure of legitimacy in social and political matters.

Most leading figures from this period were not philosophers in the strict sense. Simón Bolívar (Venezuela, 1783–1830), José Joaquín Fernández de Lizardi (Mexico, 1776–1827), Mariano Moreno (Argentina, 1778–1811), and José Cecilio del Valle (Honduras, 1780–1834) can be most accurately characterized as independence leaders rather than as philosophers. Instead of devoting their lives to developing systems of thought, they were more interested in concrete political and military action that would lead to the independence of the Iberian colonies.

Bolívar, known as the Liberator, successfully led northern South America to independence from Spain and was the founding father of five republics (Colombia, Venezuela, Ecuador, Peru, and Bolivia). Monumental deeds such as these are a central part of his legacy. Yet, his writings also helped to change the political structures in America and drew attention to the dangers confronting the newly liberated regions. In his *Carta de Jamaica* (*Jamaica Letter*, 1815), a call to independence from Spain, he complains of both a state of permanent infancy experienced by the nations of Spanish America and their dependence upon Europe. The problem of dependence is an enduring one in the Latin American philosophical tradition, shaping one of the most widespread strands of Latin American thought, the philosophy of liberation. In the *Carta*, Bolívar also touches upon the question of identity, another central theme of the tradition, prompted by the merging of indigenous and European populations and cultures.

Bolívar influenced thinkers of the contemporary period, such as the father of the Cuban revolution, José Martí (1853–1895), as well as the Mexican philosophers Samuel Ramos (1897–1959) and Leopoldo Zea (1912–2004). All of these thinkers devote considerable attention to the issues of liberation and cultural identity.

## POSITIVISM (C. 1850–1910)

Once political independence had been achieved, a somewhat more stable period of philosophical activity, known as positivism, began. With the exception of scholasticism, positivism has been the most widespread and deeply rooted current in Latin American thought to date. The depth of its impact can be explained in historical terms: It took shape just in time to address the need for nation building in the region. Positivism was in part a response to the social, financial, and political needs of the newly liberated countries of Latin America.

The European father of positivism was the French philosopher Auguste Comte (1793–1857), who attempted to develop a rigorous and systematic understanding of human beings in both their individual and social dimensions. He emphasized experience over theoretical speculation and empirical science over metaphysics. The value of knowledge rests on its practical applications: Knowledge is a servant of action and should lead to the solution of concrete problems. This practical dimension was one of the most captivating aspects of Comte's thought for Latin Americans, for they wished to overcome anarchy, eradicate poverty and disease, and place their own countries on the path of progress.

Practical considerations, however, were not the only cause of positivism's success. Cultural and theoretical reasons also played a role. Since the colonial period, Latin American philosophy had been nurtured by scholasticism and, consequently, important practical issues had been neglected. Conceptual and terminological vagueness, excessive speculation, as well as unfounded and archaic dogmatism were predominant characteristics of much of the philosophy of the region. Positivists, by contrast, emphasized principles based on experience and logical rigor, and offered the assurance of progress, insisting that their claims rested on solid empirical evidence. With positivism, the leaders of the newly liberated republics thought they would finally leave not only the political legacy of the colonization behind, but the philosophical one as well.

The movement benefited greatly from the increasing prestige of science, because it proposed to limit its methods to those used by natural scientists. It was widely believed by those who favored this perspective that a new era had begun in which scientific study would make it possible to identify the causes of social evils and to eliminate them, just as medicine had begun to do with endemic diseases.

Comte's law of the three stages captured the attention of many Latin American intellectuals. According to this law, humanity passes through a theological, a metaphysical, and a scientific or positive stage. In the theological stage, the interpretation of reality is founded on prejudice and superstition. In the metaphysical, it is characterized by speculation, and facts are either ignored or not given adequate attention. Finally, in the positive stage, superstition and speculation are replaced by the establishment of facts, and knowledge is founded on experience.

Latin American thinkers applied Comte's law to the history of their own countries. An example of this application is found in the *Oración cívica* (*Civic Oration*, 1867) delivered by the Mexican Gabino Barreda in Guanajuato. With this text in mind, President Benito Juárez named Barreda member of a committee to draft a law, approved on December 2, 1867, that gave birth to public education in Mexico. The fact that another renowned teacher, Justo Sierra (1848–1912), succeeded to Barreda's position and continued to apply positivist principles to educational policy explains the strength that this perspective had in Mexico until the fall of the dictator Porfirio Díaz in 1911. Positivism was the official philosophy in Mexico during the twenty-seven-year dictatorship, and the government was guided by Comte's slogan "Order and Progress."

The chaos and backwardness that prevailed in some Latin American countries as the power vacuums left in the wake of colonial rule were filled by *caudillos* and other nondemocratic political leaders and structures helps to explain in part why positivist teachings captivated the minds of so many intellectuals and politicians. For example, the influence of positivism can be observed in the work of the Argentine thinker and statesman Domingo Faustino Sarmiento (1811–1888). His account of civilization in *Facundo, o civilización y barbarie* (*Facundo, or Civilization and Barbarism*, 1845) is shaped by positivist principles.

Each country of Latin America had its own particular way of appropriating positivism. Latin American positivism was shaped not only by Comte, but also by the social Darwinism expounded by the English philosopher Herbert Spencer (1820–1903). Comte had a stronger impact in Brazil, Mexico, and Chile, whereas Spencer was more influential in Argentina, Uruguay, and Cuba. In some cases, preference was given to one over the other for purely political reasons. In Cuba, for example, Enrique José Varona (1849–1933) rejected Comte's ideas because they did not favor the emancipation of Cuba from Spanish rule, and he adopted instead Spencer's notion of lib-

erty. In spite of these and many other national differences, one can speak of Latin American positivism as a unified, yet evolving movement in which the influence of Comte was greater toward the beginning of the period and that of Spencer predominated toward the end.

Juan Bautista Alberdi (Argentina, 1812–1884) and Andrés Bello (Venezuela, 1781–1865) were also influenced by positivism. Positivism's legacy in Argentina remained strong because it was never involved in any political movement, so it never came to be associated with dictatorships as, for example, was the case in Mexico. Furthermore, in Argentina positivism had an effective role in the development of educational institutions and, through the work of José Ingenieros (1877–1925), acquired renown in scientific and philosophical circles.

As in Argentina, positivism played a role in the development of Brazilian education. Nisia Floresta (1809–1885), one of the founders of the positivist movement in Brazil, was director of a school in Rio de Janeiro and, upon moving to Paris, established a close friendship with Comte. Furthermore, in Brazil, positivism was associated with the founding of the Republic in 1889, and the positivist motto, “Ordem e Progresso” (Order and progress), is inscribed on the Brazilian flag. Brazil was one of the last countries of Latin America to abolish slavery (1888) in part due to the positivist movement in Brazil. An understanding of Brazil's history in the eighteenth century is impossible without an appreciation of the role that positivist thinkers such as Raimundo Teixeira Mendes (1855–1927), Miguel Lemos (1854–1917), and Luis Pereira Barreto (1840–1923) played in the founding of the Republic.

## CONTEMPORARY PERIOD (C. 1910–PRESENT)

The period following positivism is known as the contemporary period, and it can be broken down into three phases: the foundational stage, the period of normalcy, and the period of maturity.

**FOUNDATIONAL STAGE (C. 1910–1940).** This phase begins with the decline of positivism. The generation of thinkers who first rejected the central tenets of positivism became known as “the founders,” a label coined by Francisco Romero (Argentina, 1891–1962). It included: Deústua, Alejandro Korn (Argentina, 1860–1936), Enrique Molina (Chile, 1871–1964), Carlos Vaz Ferreira (Uruguay, 1872–1958), Raimundo de Farias Brito (Brazil, 1862–1917), José Vasconcelos (Mexico, 1882–1959), and Antonio Caso (Mexico, 1883–1946), among others.

The general decline of positivism stems from several factors, and the national context must be taken into consideration insofar as the predominance of any particular cause varies from country to country. Still there were causes common to all Latin America. The first of these was the disappointment that Latin American intellectuals experienced when reality did not measure up to positivism's promises and aspirations. Immediate and assured results were envisioned and anxiously awaited, but progress was slow and uncertain. To uphold general principles and criteria for the study of social problems is one thing, but it is quite a different matter to develop effective, scientifically based procedures that can be applied in order to solve concrete problems. Stark reality shattered many illusions. The ideal of a scientific knowledge of society began to crumble in the face of difficulties, and the initial naive optimism gave way to corroding pessimism.

In addition, many thinkers began to discover fundamental theoretical shortcomings in positivism. The indiscriminate application of the principle of causality led positivists to deny freedom to human beings. Theoretical objections to determinism acquired momentum in the moral realm. No one can be held accountable for an act if it is determined, the critics of positivism claimed: positivism seemed to lead to an ethical dead end.

In particular, positivism seemed to spell disaster for aesthetic creation. If humans are not free, how can they be aesthetic agents? A mechanical explanation of the creative process factored out the very meaning of artistic creation, something that many Latin Americans found unacceptable. Deústua in particular responds by developing an aesthetic theory in his influential *Estética (Aesthetics)*, (1923), in which aesthetic value is conceived as the source of all value. This “value of all values” as he calls it, is the product of free activity whose essential function consists in the creation and contemplation of an ideal aside from any practical intent. In contrast to the essentially instrumental character of other values, aesthetic value constitutes its own end, generating a completely disinterested activity, the creation of beauty.

Political considerations also factored into the general disenchantment with positivism. As already mentioned, in some countries such as Mexico, positivism was associated with a dictatorship that had been overthrown; in others such as Cuba, Comtian positivism was believed to support the colonial status quo against the possibility of independence to which many Cubans aspired. For countries that had suffered first under Spanish oppression and then under a succession of dictators, setting freedom

aside seemed too high a price to pay for the promise of progress. Indeed, freedom had become the battle flag, so if positivism could not make room for freedom, then positivism must be abandoned.

In 1909 a group of young intellectuals in Mexico, who later acquired well-deserved renown in the field of philosophy and literature, founded the “Ateneo de la Juventud” (Atheneum of youth). They studied the philosophical classics, especially Plato and Kant, and contemporary philosophers who had rejected positivism in Europe, such as Henri Bergson (1859–1941) and Benedetto Croce (1866–1952). The influence of Friedrich Nietzsche (1844–1900) and Arthur Schopenhauer (1788–1860), whose thought was a counterweight to the narrow, scientific emphasis of positivism, was also felt. Following these studies, lectures were given in which positivist doctrine was roundly criticized and new ideas were proposed.

Vasconcelos is one of the most influential figures of this generation. He was not only an accomplished philosopher, but, like so many other Latin American intellectuals, also a devoted educator and political activist. Much of his work focuses upon the meaning of Mexican culture in particular and the destiny of Latin America in general. In two of his most popular works, *La raza cósmica* (*The Cosmic Race*, 1925) and *Indología* (*Indology*, 1926), he claims that the future will be constituted by the cosmic race, a synthesis of the four basic races of the world that will emerge in the region of the Amazon basin and fulfill “the divine mission of America.” He contrasts this to the ethnic egoism and nationalism that dominates in Anglo-Saxon culture and claims that the new race of which he speaks will be characterized by a universalist spirit based on love.

Two other key figures are Caso in Mexico and Korn in Argentina. They are particularly important because they functioned as influential teachers and mentors of the generation that followed them. The first developed a moral theory based on the principle that there are two basic attitudes toward existence: One is based on the notion of existence as economy, where action is dictated by maximum advantage with minimum effort; the other is guided by disinterest, where action is dictated by maximum effort with least concern for advantage. The first is a positivist morality, the second is a morality based on love. In a somewhat similar vein, Korn developed a philosophy of creative freedom inspired by Kant. Although the physical realm operates according to necessary laws, subjects can formulate ideals and act according to them, thus resisting the tyranny of nature.

Crucial influences in the overcoming of positivism and its legacy were vitalism and intuitionism, especially the versions imported from French philosophers such as Émile Boutroux (1845–1921) and Bergson. Vitalism was a metaphysical position that conceived reality in terms of life. Intuitionism was an epistemic view in which knowledge, particularly about values, is based on intuition. Representative of this move away from positivism’s narrow approach was the work of Vaz Ferreira. In books such as *Conocimiento y acción* (*Knowledge and Action*, 1907), *Lógica viva* (*Vital Logic*, 1910), and *Fermentario* (*Fermentary*, 1938), he attacks the narrow, purely rational concept of knowledge that excludes the dynamic vitality of reality. He also pioneered the discussion of feminist issues in *Sobre feminismo* (*On Feminism*, written between 1914 and 1922, but first published in 1933).

An important force in the transition from positivism to vitalism was the Spanish philosopher José Ortega y Gasset (1883–1955). But there were also others, who belonged to what has come to be called the Generation of 98. The year 1898 marked the end of Spain’s colonial empire, yet it also signaled the opening of a promising, new intellectual movement. The famous generation of 1898 gave Spain some of its most brilliant intellectuals, including two of its greatest philosophers, Ortega and Miguel de Unamuno (1864–1936).

Many thinkers in Spain, a country located at the geographical margins of Europe, struggled to be recognized as European, but Unamuno was more interested in developing the notion of *hispanidad* (Hispanicity) and to the *hispanización* (Hispanization) of Europe. The notion of *hispanidad* came to serve as an important bridge between the philosophy of Spain and Latin America. Interest in analyzing the meaning of *hispanidad* has continued into the twenty-first century, with philosophers in the United States developing arguments concerning rights for Hispanics and debating the very meaning of the term “Hispanic.”

Like Unamuno, Ortega also made the intellectual, political, and social situation of Spain central to his philosophy. He developed what has become known as a “philosophy of circumstance,” well captured in the famous lines: “*Yo soy yo y mis circunstancias y si no las salvo a ellas no me salvo yo*” (I am myself and my circumstances, and if I don’t save them, I cannot save myself). The idea is that the self is not an entity apart from its context. Integral to this view is the notion that all knowledge is perspectival—that is, it is the expression of a view from a particular perspective. Ortega’s perspectivism came to play a

critical role in the work of several Latin American philosophers.

**THE FORGERS.** The thought of the generation that followed the founders was shaped by ideas imported from Spain, France, and Germany, and Ortega is generally credited with having introduced them, particularly German philosophy, into Latin America. The extraordinary impact of Max Scheler (1874–1928) and Nicolai Hartmann (1882–1950) can be explained only through Ortega's influence. This group of philosophers has been characterized by Francisco Miró Quesada (Peru, b. 1918), as "the generation of forgers" because of the major role they played in setting the parameters for the subsequent development of Latin American philosophy. A major figure of this generation was Samuel Ramos (Mexico, 1897–1959). He focused upon Mexican culture, thereby inspiring interest in what is culturally unique to Latin American nations. Ramos' book, *El perfil del hombre y la cultura en México* (Profile of man and culture in Mexico, 1934), was the first attempt at interpreting Mexican culture. Francisco Romero was also an important thinker who developed an elaborate philosophical anthropology in his *Teoría del hombre* (Theory of man, 1952). He sought to frame a view of human beings in terms of universal notions such as intentionality and spirituality, rather than the culturally specific parameters used by Ramos.

Throughout the history of Latin American thought there has been a tension between philosophers who focus on the universal human condition and those who emphasize particular cultural circumstances. In Mexico, for example, many philosophers have discussed the impact of the colonization on the development of culture in Mexico. And in *Siete ensayos de interpretación de la realidad peruana* (Seven interpretative essays on Peruvian reality, 1928), the Peruvian Carlos Mariátegui (1894–1930) proposed an interpretation of Marxism that emphasized the particular conditions that characterized the Peruvian situation. This particularist tendency grew in part as result of a historical event that brought the Spanish and Latin American philosophical traditions into even closer contact with one another and heralded yet another stage in the latter.

The historical circumstances of Spain in the twentieth century were complicated, and part of the influence that Spanish thinkers came to have upon the development of philosophy in several Latin American countries can be attributed to the political upheaval caused by the Spanish Civil War (1936–1939) and the ensuing dictator-

ship of Francisco Franco (1939–1975). Many of the most important Spanish philosophers of this period were driven into exile during the years of Franco's oppressive dictatorship and several of them settled in Latin America.

**THE "TRANSTERRADOS" AND THE PERIOD OF NORMALCY (c. 1940–1960).** During the late 1930s and 1940s, due to the upheavals created by the Spanish Civil War, a significant group of thinkers from Spain arrived in Latin America. These philosophers became known as the *trasterrados* (trans-landed). Seeking refuge from Franco's dictatorship, they settled in various countries of Latin America. Among them were Joaquín Xirau (1895–1946), Eduardo Nicol (1907–1986), José Ferrater Mora (1912–1991), José Gaos (1900–1969), Luis Recaséns Siches (1903–1977), and Juan D. García Bacca (1901–1992). Their presence helped to break some of the national barriers that had existed in Latin America before their arrival. The conception of *hispanidad* that they inherited from Unamuno and the need to establish themselves in their adopted land helped the process; they went from country to country, spreading ideas and contributing to an ever broadening philosophical dialogue. Their influence showed itself most strongly when the generation born around 1910 reached maturity.

Gaos was one of the most influential *trasterrados*. He was a student of Ortega and became the teacher of one of Mexico's most important philosophers, Leopoldo Zea. Gaos encouraged Zea to study the history of Mexican thought, and this resulted in one of Zea's most important books, *El positivismo en México* (Positivism in Mexico, 1943). Through Gaos, Ortega had a strong influence on Zea's views. Following Ortega's insights that in order to understand ourselves, we must understand our circumstance, and that all knowledge is perspectival, Zea turned to the meaning of the Latin American circumstance for the development of the philosophy of the region.

Zea's philosophy was also influenced by Ramos's work. The latter's existential, psychoanalytic approach to the problem of cultural identity was transformed by Zea into a critique of philosophy and the articulation of a *mestizo* (mixed) consciousness. The term *mestizo* points to issues associated with race and culture, opening a philosophical discussion concerning the identity of persons who share Spanish and indigenous heritage. The source of this line of questioning can be traced back to the events following the colonization, when the Spaniards began to mix with the indigenous people to create what has come to be known as a *mestizo* race and culture. Zea's

notion of *mestizaje* had a strong influence on the Argentine philosopher Arturo Andrés Roig (b.1922) and the Peruvian Miró Quesada. The relation between these thinkers constitutes an example of a growing philosophical Pan-Americanism. During this period, philosophers from different countries in Latin America began to respond to each other and to interact critically with one another.

**PERIOD OF MATURITY (C. 1960–PRESENT).** This Pan-American trend continues to the present and has been further supported by the activities of various organizations founded to facilitate meetings and publications. From 1960 to the present, the level of philosophical activity in several Latin American countries has improved significantly. This is due, in part, to the institutionalization of philosophy. The number of national philosophical societies and of centers, institutes, faculties, and departments that have as their exclusive end the teaching and investigation of philosophy has increased substantially as have the number of philosophy journals. All of this activity has begun to awaken interest outside of Latin America, and indeed to give rise to a diversification of philosophical trends within Latin America itself. Three trends in particular illustrate the current situation of Latin America: philosophical analysis, liberation philosophy, and discussions of identity.

**Philosophical analysis.** Analytic philosophy is characterized by a preoccupation with language, a strong interest in logic, a positive attitude toward science, and a general mistrust of metaphysics. Its founders are G. E. Moore (1873–1958), Bertrand Russell (1872–1970), Ludwig Wittgenstein (1889–1951), and the members of the Vienna Circle. Analytical philosophy is often contrasted to Continental philosophy, which has its roots in France and Germany and is based on the thought of such figures as Hegel, Nietzsche, Jean-Paul Sartre (1905–1980), and Martin Heidegger (1889–1976). Continental philosophy was disseminated earlier and more widely than analytic philosophy in Latin America. Even in the early twenty-first century, authentic Latin American philosophy is often taken to be concerned exclusively with issues of Latin American cultural identity and liberation, and so to have little in common with the analytic tradition. Yet, this is a misconception.

The groundwork for the favorable reception of analysis in Latin America can be traced back to positivism. In the 1920s, key texts from the analytic tradition, such as G. E. Moore's *Ethics* and Bertrand Russell's *The Problems of Philosophy*, were translated into Spanish.

While marginalized from its inception, philosophical analysis has provided a robust methodological alternative to Ortega's perspectivism and Continental philosophy.

The fruits of the interest in analytic philosophy became evident in the 1940s, when Vicente Ferreira da Silva (1916–1963) published a manual of mathematical logic in Brazil, and Miró Quesada published one in Peru. Miró Quesada has maintained a balanced view of philosophy throughout his career. His works, *Despertar y proyecto del filosofar latinoamericano* (The awakening and project of Latin American philosophy, 1974) and *El problema de la filosofía latinoamericana* (The problem of Latin American philosophy, 1976), testify to his view that philosophy must combine both solid philosophical analysis and a historical approach that takes into account the particular circumstances of Latin America.

In Buenos Aires, Hans A. Lindemann, who had connections to the Vienna Circle, brought attention to philosophical analysis in Argentina, as the work of Gregorio Klimovsky (b. 1922) and Julio Rey Pastor (1888–1962) illustrates. In *El punto de partida del filosofar* (Philosophizing's point of departure, 1945), Risieri Frondizi (Argentina, 1910–1983) offered a serious critique of logical positivism while displaying the influence of philosophical analysis.

In the 1960s, philosophical analysis was integrated into many philosophy departments throughout Latin America. Argentina continued to be a center of this kind of philosophy. Mario Bunge's (Argentina, b. 1919) *Causalidad* (Causality, 1961) and Tomás Moro Simpson's *Formas lógicas, realidad y significado* (Logical forms, reality and meaning, 1964) are examples of philosophical analysis in Argentina. In 1972 Eduardo Rabossi (b. 1930), who has published extensively on human rights, founded the *Sociedad Argentina de Análisis Filosófico* (SADAF), which, as its name indicates, is committed to the advancement of the analytic tradition and publishes the journal *Análisis Filosófico*.

The influence of philosophical analysis is also evident in Brazil, particularly in *Manuscrito*, a journal published by the Center of Logic, Epistemology and Philosophy of Science at Campinas. In Mexico, Alejandro Rossi (b. 1932), Fernando Salmerón (1925–1997), and Luis Villoro (b. 1922) founded *Crítica* in 1967, a journal devoted to discussions from an analytic perspective. And the Instituto de Investigaciones Filosóficas of Mexico has been actively engaged in supporting the work of analytic philosophy.

While we can speak of a period of stability in the development of philosophical analysis in Latin America, there has been widespread political instability in many countries of the region. As a result, many outstanding analytic philosophers had to leave Latin America. Bunge was a professor of philosophy at the University of Buenos Aires from 1957 to 1963, but has worked at McGill University in Montreal since 1966. Hector-Neri Castañeda (Guatemala, 1924–1991) worked in the United States for most of his career, and Ernest Sosa (b. 1940) and Jorge Gracia (b. 1942) came to the United States from Cuba. Apart from contributions in the history of philosophy, metaphysics, and hermeneutics, Gracia has published in many areas of Latin American philosophy, including the impact of philosophical analysis in Latin America. Sosa works primarily in epistemology and metaphysics and was recently elected president of the Eastern Division of the American Philosophical Association; he is active in the promotion of analytic philosophy in Latin America.

Philosophical analysis is generally recognized as an important philosophical current in Latin America and analytic philosophers have the support of several institutes and journals, but there is some animosity in some quarters against this philosophical approach. Indeed, some Latin American philosophers have explicitly accused analytic philosophers of turning a blind eye to social injustice and the pressing political and economic issues that plague the region.

**The philosophy of liberation.** One current within the Latin American philosophical tradition that puts social concerns at the center is the philosophy of liberation. For this movement, the fundamental task of philosophy consists in the social and national liberation from the unjust relations, such as that of dominator-dominated, which have traditionally characterized Latin American philosophy. The philosophy of liberation is rooted in the political discourse of marginalized and exploited segments of society.

This current grew out of liberation theology, which in turn began in Peru and Brazil. Its origins can be traced to the 1970s in Argentina, to a group of thinkers that included Arturo Andrés Roig (b. 1922), Horacio Cerutti Guldberg (b. 1950), and Enrique Dussel (b. 1934). Because of the political turmoil during this period, many of these philosophers were forced into exile, thus disrupting the continuity of the movement and leading to the creation of various distinct strands of the philosophy of liberation. In spite of differences, however, they share a common concern with what it means to do philosophy from the periphery—that is, from the condition of dependence that these thinkers claim characterizes Latin

American culture. The philosophy of liberation has been influenced by Marxist and Catholic ideas and is one of the most active philosophical currents in Latin America.

**Identity.** The problem of identity in Latin American philosophy has two dimensions: the identity of Latin American thought and cultural identity. In dealing with these aspects of the problem, philosophers tend to favor either what may be called a national approach or a continental—in a purely geographical sense—approach. Mariátegui, for example, addressed Peru's reality, applying Marxist principles in order to solve the problems facing Peruvians, *not* Latin Americans in general. In contrast, the Cuban thinker José Martí addressed issues of *nuestra América* (our America), emphasizing what is common to all the nations that comprise the region. Both thinkers prepared the way for the exploration of what it means to speak of Latin America and of Latin American philosophy.

The question of the existence and character of Latin American philosophy was first explicitly raised by Zea and Frondizi in the 1940s, although related questions had been alluded to even earlier by Alberdi. According to Alberdi, a Latin American philosophy must have a social and political character intimately related to the most vital needs of the continent. Because he conceives philosophy as an instrument for social, political, and economic change, Alberdi rejects metaphysics and other “pure and abstract” philosophical fields.

Zea's work extended the discussion of the meaning of Latin American philosophy. His culturalist perspective, according to which philosophy is intimately related to the culture and history from which it emerges, has won many adherents. Supporters find in this approach to defining philosophy a way of opening space for contributions that do not fall under the umbrella of the European and Anglo-American philosophical traditions under whose shadows they tend to remain marginalized. Abelardo Villegas (Mexico, 1934–2001), Ricarte Soler (Panama, 1932–1994), and Guillermo Francovich (Peru, 1911–1990) are just three of the many philosophers who have adopted Zea's view. In Venezuela, Ernesto Mayz Valenilla (b. 1925) has addressed some of these issues both in his work and in his capacity as public educator.

The problem facing philosophers as they grapple with the issue of the identity of Latin American nations, peoples, and intellectual traditions has become even more complicated as these discussions have entered the United States. Philosophers concerned with the place of Hispanics or Latinos in the United States explore questions related to what happens to the identity of Mexicans, Cubans, Colombians, and other Latin Americans who

immigrate to the United States. Is there a term that can capture the identity of this diverse group? If so, which term? Or should we give up on the enterprise altogether? These questions take on particular relevance in light of the discussion of group rights. Latin American thinkers working in the United States on such issues include Ofelia Schutte (Cuba, b. 1945) and Gracia.

Latin American philosophy has a rich and variegated history. Latin American philosophers have a tradition of concern for the specific social and political problems that plague the population of the Americas. But they remain engaged with the universal concerns that have characterized philosophy since its inception—problems of truth, goodness, and justice, among others—that are not the product of any particular political structure, social context, or geographical location.

## LAVATER, JOHANN KASPAR (1741–1801)

Johann Kaspar Lavater, the German-Swiss poet, physiognomist, and theologian, was born in Zürich. He studied at the gymnasium there under the literary critics Johann Jakob Bodmer and Johann Jakob Breitinger. Later, in northern Germany, he attended the lectures of the Protestant pastor Johann Jakob Spalding, who, influenced by the Earl of Shaftesbury and the English moralists, sought to reconcile reason and sentiment and stressed the moral and religious conscience. While in northern Germany Lavater also met Johann Georg Sulzer, Moses Mendelssohn (whom he later tried to convert to Christianity), the dramatist Friedrich Gottlieb Klopstock, and other persons of note. Returning to Zürich in 1764, he held various posts in churches there from 1769 on. He traveled widely in Germany, was acquainted with many culturally important people, and was one of the most sought-after and famous persons of that time. As a poet, he published a volume of religious verse, *Christlicher Lieder* (1771), and two epic poems in the manner of Klopstock, *Jesus Messias* (1780) and *Joseph von Arimathia* (1794). Because of his opposition to the Zürich government, Lavater was forced to move to Basel in 1796. He returned, only to be wounded during the French capture of Zürich in 1799. He died of this wound in 1801.

Lavater is chiefly known as a physiognomist. His theories were expounded in two main works, *Von der Physiognomik* (Leipzig, 1772) and *Physiognomische Fragmente zur Beforderung der Menschenkenntnis und Menschenliebe* (Physiognomic fragments for furthering the knowledge and love of man; 4 vols., Winterthur, Switzerland, 1775–1778). Johann Gottfried Herder and Lavater's close and longtime friend Johann Wolfgang von Goethe both collaborated on the latter work. Lavater claimed independence from traditional physiognomy dating from the time of Aristotle, but his independence was chiefly a mat-

ter of superficial knowledge of the tradition. He supported the classical view that the human body is influenced in shape by the character of the person, and vice versa; but his criteria were inconsistent and confused. There were two main reasons for his unprecedented success: First, his lively and simple manner of exposition that followed the pattern of the “popular philosopher”; and second, the psychology of character at the base of his theory.

Lavater stressed “feeling” and such spiritual qualities as inspiration and creative genius, which were being widely discussed in the eighteenth century. The native language of genius, and of virtue and wisdom, could become known only by studying the human form. Man is the measure of truth. That which harmonizes in form with a man, and is a part of him, is what exists for him. There is no absolute truth, but only a subjective experiencing. Therefore feeling should be cultivated, as it is in the genius. Lavater’s psychology of genius, which gave emotions a place beside reason, was an important link between Pietism and sentimentalism on the one hand, and *Sturm und Drang* on the other. Lavater was severely criticized—notably by Georg Christoff Lichtenberg—but his handsomely printed volumes, with their illustrations, and his complimentary analyses of various influential contemporary figures were widely read.

As a writer of religious and devotional literature, Lavater was equally influential. His religious views were based on a belief in inner light, making his subjectivism a mystical and sentimental anthropomorphic theology. God is what satisfies the needs of man. The Bible is historically true but it is to be interpreted subjectively. Lavater was strongly convinced of the magical force of grace and prayer, and was strongly interested in miracles and prophecies. He was therefore drawn to spiritualism and mesmerism.

## LAVELLE, LOUIS

(1883–1951)

Louis Lavelle, the French philosopher, was born in Saint-Martin-de-Villéréal, in southwestern France. He was professor of philosophy at the Sorbonne from 1932 to 1934 and at the Collège de France from 1941 until his death. In a time of reaction against speculative system-building, Lavelle boldly elaborated an extensive system combining elements of the French *philosophie de l'esprit* and existentialism. Convinced that the modern world needs basic security, Lavelle, like other existentialist thinkers, sought philosophical and moral certitude in the experience of the self, “pure inwardness,” and “absolute existence.” Unlike such philosophers as Jean-Paul Sartre, who “disintegrated” the human universe inherited from tradition, Lavelle, like Karl Jaspers and Karl Barth, attempted to “reintegrate” the basic experiences of humanity in a novel form. In his spiritualistic interpretation of the self Lavelle continued the French tradition of Nicolas Malebranche, Maine de Biran, Octave Hamelin, Henri Bergson, and Maurice Blondel.

### METAPHYSICS OF PARTICIPATION

Metaphysics was for Lavelle “the science of spiritual inwardness.” According to him, Immanuel Kant had shown that we cannot find true reality on the side of the object, or thing, because objects and the world they compose cannot have independent existence. The essence of things resides in their relation to a being for whom they are “objects.” Consequently, in the search for true or

absolute reality we must turn toward the act of consciousness, the “inwardness” of the human being. Thus Lavelle’s central preoccupation was to discover and describe the fundamental relation between our innermost being and the Absolute.

Lavelle pointed out that there is a “primitive act” upon which our very being depends, as well as the being of the entire world. It is our primordial experience of being part of the world, in which act we find ourselves also “participating” in something that infinitely transcends us—the Act (Absolute Being, God). From a subtle dialectic description of this spiritual act of “participation” flow the broad lines of Lavelle’s doctrine.

### ONTOLOGY OF SPIRITUALISTIC EXISTENTIALISM

The originality of Lavelle’s conception of the nature of beings in their relation to Being consists in his introducing a dynamic and “actualistic” content into the traditional themes of Aristotelian ontology. His approach yields a finalistic and optimistic view of the universe and human destiny.

All experiences of humankind emerge against the background of the limited individual being, participating in the Absolute Being. By their relation to participation, which is constant and eternal, individual beings establish their relation to the world, and through the notions of essence and existence they establish their spiritual identity. The Absolute Being is pure actuality, the infinite source of existential dynamism, and an endless reservoir of all possible forms or essences, from which individual beings receive their own limited existence. In spite of this direct and continuous dependence of the individual on his source, actualism is reconciled in Lavelle’s thought with temporal progression, dynamism with formal immobility, and human freedom is safeguarded by the self-creativity of the individual. Indeed, from the human point of view, participation is a pursuit of an ideal that constantly moves ahead of our efforts. In this pursuit we create our spiritual self, and our experiences, moving onward, progressively acquire a unique form. Our effort in life is meant to discover this form, which has its prototype in the reservoir of Being and is our spiritual essence. The accomplishment of our essence at our death means the radical passage from limited existence into transfinite Being. Thus participation appears as the means of humanity’s ultimate redemption, toward which everything occurring in the universe converges.

The world is the interval that separates pure Act (Being) from the limited act of participation (human

existence). Matter, in limiting the spirit, offers the resistance necessary for the self to transcend itself. The world comprises three modes of reality: the world of things, that of ideas, and that of individual beings (consciousnesses). The material world plays the necessary role of separating beings; ideas give spiritual meaning to things. The world of individual consciousnesses is necessarily conscious because the essence of the Absolute Being from which they proceed is itself perfect inwardness; as such it is eternally fecund and intended to communicate the creative act to beings which, in turn, propagate it in self-creation.

### ETHICS OF CONSENT

In Lavelle’s moral philosophy an unusual meaning is given to existential themes, such as freedom, human destiny, and solitude. Lavelle had a constructive conception of man’s vocation and of the ideal of life.

Freedom is the essence of man. But whereas the Absolute Act is synonymous with absolute freedom, man, the participating act, is limited by the “natural spontaneity” of the instinct. Consequently, the life of the spirit, which he proposed as the ideal of human life, is a fighting toward gradual liberation from the passivity peculiar to instinct. We become fully human by subordinating natural spontaneity to reflection and rational discipline. Human freedom originates in this process; and this conversion of spontaneity into freedom is the real vehicle of participation. The spiritual being, like the Leibnizian monad, is endowed with potentialities for the accomplishment of its preestablished essence. Our vocation is to seek to make our actual selves coincide with the “better part of ourselves,” which represents these potentialities. This self-searching and self-controlling effort presupposes an “act of consent” to our vocation of the spirit. In opposition to other existentialist thinkers who glorify the “exceptional instant,” Lavelle rehabilitated everyday existence, seeing even in the least significant instant an opportunity for consent to the self-creative effort and, thereby, an opportunity for participation in the Absolute.

Finally, the theme of solitude was reconciled with that of human communion insofar as the ideal of wisdom was seen to lie in the union between a certain asceticism and everyday life and love.

## LAVOISIER, ANTOINE

(1743–1794)

Antoine Lavoisier played the central role in what has come to be known as the chemical revolution. He is credited with establishing that oxygen is an element and water its compound with hydrogen, refining experimental methods in chemistry, reforming chemical nomenclature along systematic lines, defining *element* operationally, and denying phlogiston a place in chemical explanation.

## EARLY LIFE AND WORK

Lavoisier was born into a wealthy family of lawyers in 1743, and in preparation for a legal career attended the Collège des Quatre Nations (or Collège Mazarin), earning a baccalaureate in law in 1763. He pursued scientific interests under the guidance of the geologist Jean-Étienne Guettard (1715–1786), a family friend, and attended Guillaume-François Rouelle's (1703–1770) popular and influential lectures on chemistry and mineralogy at the Jardin du Roi. From 1763 Lavoisier assisted Guettard on field trips for the first geological survey of France. His first chemical work was a study of gypsum and plaster of Paris, which was read to the Academy of Sciences in 1765, to which he was elected in 1768. That year Lavoisier also joined the Ferme Générale, a private company collecting indirect taxes in return for a fixed payment to the Crown. This investment would secure his fortune, but also prove his downfall. In 1771 he married Marie Anne Paulze, the fourteen-year-old daughter of a senior member of the Ferme. Marie became a significant collaborator: She learned English to translate important scientific papers, assisted in the laboratory, and trained in the visual arts, providing the engravings for Lavoisier's *Traité Élémentaire de Chimie* (1789).

Lavoisier was active outside of chemistry, especially in economic and farming reform. As an academician, he pursued many technological projects in the service of the state, helping to investigate water supply and storage, food purity, ballooning, bleaching, and ceramics and to develop the metric system. From 1776 he was in charge of the production and administration of gunpowder, working from a laboratory in the Royal Arsenal.

Lavoisier's contributions to chemistry began at a time when advancing experimental techniques made clearer the atmosphere's active role in chemical reactions, but phlogiston, the principle of inflammability, still provided the prevailing framework for understanding combustion and calcination (the formation of metal oxides). In 1772 Louis-Bernard Guyton de Morveau (1737–1816)

reported to the Academy of Sciences that metals increase their weight on calcination. This was in tension with the phlogistonists' view that combustion and calcination involved loss of phlogiston to the air. Guyton de Morveau argued that the light phlogiston must "buoy up" the metal, but Lavoisier saw calcination instead as fixation of air in the calx. In the long and carefully constructed series of experiments that followed, Lavoisier studied the combustion and calcination of metals and nonmetals, measured the volumes of air absorbed or evolved, and weighed and investigated the solid products and the residual air. By 1778, drawing also on the experimental work of others, he was convinced that a particular component of air was involved in combustion, the "purest part of air" or "eminently respirable air," which combines with carbon to form fixed air (carbon dioxide). Lavoisier also noted during the 1770s that air was absorbed in the formation of phosphoric, sulfuric, and nitric acids and of fixed air, which was weakly acidic in solution. In papers read to the Academy of Sciences between 1776 and 1779 he concluded first that the acids were a chemical genus, containing air combined with different principles, and later that "eminently respirable air" contains the principle of acidity, which he called *principe oxigine* (later to become *oxygène*). Water he identified as oxygen combined with "inflammable air" (which he renamed hydrogen). Oxygen the gas was not *itself* the principle of acidity, though: Lavoisier saw gases also as a chemical genus, their common constituent being caloric, the matter of heat. Thus in combustion, substances combine with the oxygen principle, releasing caloric from oxygen gas, which explained why heat was evolved in the process. Experiments on animal respiration convinced him that respiration is a slow version of combustion, and in 1785 he extended his theory of acidity, accounting for the solution of metals in acids as wet calcination.

## CHEMICAL REVOLUTION

These three theories—of combustion, acidity, and the gaseous state—gave Lavoisier a framework comprehensive enough to deny phlogiston its explanatory role. In 1785 he read "Réflexions sur le Phlogistique," a direct attack on the theory, to the Academy of Sciences. In 1787 he published, with Guyton de Morveau and others, a new nomenclature for chemistry, replacing a jumble of uninformative traditional names with a system for naming compounds based on their composition, reflecting the latest discoveries. This is largely still in use in modern chemistry.

Lavoisier published his most influential work, *Traité Élémentaire de Chimie*, in 1789. This combined a clear presentation of his own theories of gases, of combustion and acidity in part I, with (in parts II and III) a summary of less controversial material on acids, bases, and salts and on experimental methods. In the preface, he introduced his empirical definition of *elementhood*: rejecting the traditional speculations about the "simple substances," he proposed to treat as simple any substance that had not yet been decomposed in the laboratory.

After 1789 political revolution in France intervened increasingly in Lavoisier's activities, curtailing his scientific researches, though at first he was sympathetic to its aims. Scientific and administrative institutions of the ancien régime, in which he had played a prominent (though liberal and reforming) role, were successively abolished: the Ferme Générale in 1791 and the Academy of Sciences in 1793. Members of the Ferme were arrested in November 1793, and on May 8, 1794, were convicted of adulterating tobacco and withholding taxes from the government. Lavoisier was executed that same day, just after his father-in-law.

Lavoisier's achievement raises important historiographical and philosophical questions about progress in science. Lavoisier himself, writing in 1773, foresaw a revolution in chemistry, and his name appears throughout Thomas S. Kuhn's *Structure of Scientific Revolutions* (1970). In this technical sense the defeat of the phlogiston theory has been called a scientific revolution because: (1) it involved wholesale revision to theoretical interpretations of empirical evidence and accepted views of the relative simplicity of whole classes of substances (e.g., metals and their calxes); and (2) it was accompanied by a major reform of chemical nomenclature that embedded the oxygen theory in the very language of chemistry. The importance of his empirical definition of *elementhood* is less clear. It was not original to him, and it applied only selectively to his own list of elements.

## LAVROV, PĚTR LAVROVICH (1823–1900)

Pětr Lavrovich Lavrov was a Russian philosopher and social thinker, a major theoretician of Russian Populism and the leading exponent of a distinctive form of positivism in nineteenth-century Russian philosophy (also elaborated by Nikolai Mikhailovskii). Lavrov was born in Melekhov, the son of a landed gentleman and retired artillery officer. He was sent to the Artillery School in St. Petersburg in 1837 and received his commission upon graduating in 1842. In 1844 he joined the faculty of the Artillery School, and for more than twenty years (during which he rose to the rank of colonel), he taught mathematics and the history of science at military institutions in St. Petersburg. At the same time Lavrov read widely in philosophy and gained a reputation as a writer—first for his poetry and after 1858 for his scholarly essays in philosophy. In the 1860s, the increasing liberalism of his social views aroused the suspicion of the tsarist authorities. Arrested in 1866, he was exiled to the provinces in the following year. In 1870 he fled to Paris, where he played an active role in the Commune of 1871. After sojourns in London and Zürich, he settled in Paris in 1877. A friend of Karl Marx and Friedrich Engels, Lavrov became the voice of Russian socialism abroad and a revered figure in the international socialist movement. He died in Paris.

Lavrov developed an early interest in socialism through reading François Marie Charles Fourier and other leading socialists; he was particularly attracted to the ideas of Pierre-Joseph Proudhon and Aleksandr Herzen. Philosophically, Lavrov's initial scientific orienta-

tion evolved in the direction of positivism rather than in the direction of the "materialism" that was prevalent in Russian radical circles of the day, among such thinkers as Nikolai Chernyshevskii and Dmitrii Pisarev. However, his positivistic philosophy was based more on German models than on Auguste Comte. Lavrov did not become acquainted with Comte's writings until the middle of the 1860s; by then his thinking had been given strong direction by a close study of Immanuel Kant, G. W. F. Hegel, the neo-Kantian Albert Lange, and "young Hegelians" such as Ludwig Feuerbach and Arnold Ruge.

In his first important philosophical writings, which consisted of several long essays written between 1858 and 1861, Lavrov criticized materialism as a metaphysical system that unnecessarily restricts science to matter in motion. Distinguishing between material phenomena, conscious phenomena, and historical phenomena, he maintained that phenomena of the last two classes cannot be dealt with by the methods of the natural sciences. The phenomena of consciousness, in particular, require a "subjective," introspective method, and furthermore, these phenomena must be regarded as scientifically primary, since every investigator must begin from the facts of his own consciousness. Calling this approach "anthropologism," Lavrov developed it into a neo-Kantian positivism that, while it rejected supernaturalistic metaphysics and religion, did not reject moral imperatives. It stressed the thought and action of the free individual who finds in his own consciousness an absolute sanction to strive toward the realization of moral ideals such as individual dignity and social justice. While material phenomena are governed by universal natural laws, man's conscious conviction that he is free is inescapable and thus may be taken as a foundation for practical philosophy. Moral ideals are ultimately grounded in man's striving for pleasure, but in the consciousness of the cultivated individual they present themselves as nonegoistic, universal imperatives.

In his best-known philosophical work, *Istoricheskie pis'ma* (Historical letters), first published serially in the magazine *Nedelia* (Week) in 1868 and 1869, Lavrov continued his attack upon materialistic reductionism by applying "anthropologism" to history. Arguing that man can view history only "subjectively" and teleologically, he defined the goal of history as the physical, moral, and intellectual development of the individual. On this basis he maintained that the "critically thinking individuals" who have already achieved such development have a moral obligation to extend the opportunity for development to the masses, whose toil has given the privileged

few the leisure and the resources needed for self-cultivation. Lavrov asserted that in coming to understand the defects of existing social institutions and in actively striving to reform them, the “critically thinking individuals” both discharge their “debt to the people” and serve as the moving forces of history. He envisaged a future in which all social institutions will conform to man’s natural needs and the coercive institutions of the state will be all but eliminated. *Istoricheskiye Pis'ma* had a great impact on the Russian revolutionary youth of the 1870s.

Lavrov was able to develop his socialist program more explicitly abroad, where he was free from tsarist censorship. From 1873 to 1876 he edited the journal *Vpered!* (Forward!), the chief organ of Russian Populist socialism—a form of agrarian socialism, inspired by Herzen and Chernyshevskii, which stressed the Russian village commune and the possibility it afforded Russia of moving directly to a socialist order, thus bypassing the evils of capitalism. Lavrov’s political theory was further elaborated in *Gosudarstvennyi element v budushchem obshchestve* (The state element in future society), published in London in 1876. Acknowledging the need for revolution, Lavrov at first stressed the value of preparatory education and propaganda. Later he came to condone revolutionary terrorism and was associated with the Russian extremist party, *Narodnaia volia* (The people’s will).

In his later socialist views, which were closer to those of Marx, Lavrov gave more attention to class conflict and to the process of production, but he never adopted a fully Marxist view of history or social dynamics. His emphasis remained moralistic and individualistic, with its focus on the development and activity of the “critically thinking individual.” The philosophical outlook reflected in Lavrov’s *Istoricheskiye Pis'ma* remained fundamentally unchanged in his last major work, which consisted of two lengthy introductory volumes of an unfinished intellectual history titled *Opyt istorii mysly novogo vremeni* (Essay in the history of modern thought; Geneva, 1894).

## LAW, PHILOSOPHY OF

In addition to the detailed survey entries *Philosophy of Law*, *History of*, and *Philosophy of Law, Problems of*, the Encyclopedia includes the following entries in which legal theories and concepts are discussed: *Analytic Jurisprudence*; *Historical School of Jurisprudence*; *Justice*; *Legal Positivism*; *Legal Realism*; *Natural Law*; *Property*; *Punishment*; *Responsibility*; *Moral and Legal*; *Rights*; and *Sovereignty*. See “Philosophy of Law, History of,” and “Philosophy of Law, Problems of,” in the index for entries on philosophers and legal theorists who have concerned themselves especially with questions in the philosophy of law.

## LAW, WILLIAM

(1686–1761)

William Law, the English devotional writer, controversialist, theologian, and mystic, was a fellow of Emmanuel College, Cambridge. As a nonjuror, he refused to take the oath to King George I and thus terminated his career at the university and in the church. For a time he was a tutor in the household of Edward Gibbon, grandfather of the historian. His later life was virtually without incident, and after years of retirement, he died in his native village of King's Cliffe, Northamptonshire.

Law is best known as a devotional writer and especially for his *A Serious Call to a Devout and Holy Life* (1728); but his importance in the history of thought lies elsewhere, in his resistance to latitudinarianism, his defense of morality, his attack on deism, and his mystical writings.

Law was a formidable controversialist, and in his *Three Letters to the Bishop of Bangor* (1717) he brought remorseless logic to bear on Benjamin Hoadly's lax view of the nature of the church. Bernard de Mandeville had contended in the *Fable of the Bees* that private vices are actually public benefits; Law subjected the work to rigorous examination and showed that the canons of morality cannot be understood in terms of such specious sophistries. His most serious and celebrated work was his attack on deism. In *Christianity as old as the Creation*, Matthew Tindal argued that reason is the only test of truth; insofar as Christianity is valid, it rests on rationalist principles that owe nothing to revelation. Law's *Case of Reason* was a closely argued refutation of the prevailing rationalism of the period. Human reason is not able, by itself, to encompass all knowledge, nor is it sufficient to test all truth. Those who exalt natural religion are exposed to the same criticism as those who accept revelation without question. The universe is less simple and the ways of God are more mysterious than the arrogance of rationalism admits. Law shared with George Berkeley and Joseph Butler the credit for terminating the active phase of the deistic controversy.

Law's later writings reflect the profound influence that mysticism (especially as expounded by Jakob Boehme) came to exercise over his thought. He reached the conclusion that real knowledge is "the communion of the knowing and the known." To convey his new insights, Law organized his teaching in the form of "myth." He believed that mysticism gives birth to symbols within which its truth can live. Law felt that he had penetrated to a deeper understanding of human nature and that it

could best be interpreted through a grasp of the meaning of the myth of the Fall on the one hand and through an understanding of divine self-communication in love on the other ("Love is the first *Fiat* of God"). Law's mystical teaching about life was related to a restatement of orthodox Christianity. He expounded the atonement with great beauty and insight and believed that the Trinity was the most illuminating way to describe the self-unfolding of the Eternal.

Law's mystical writings were perplexing to thinkers of the eighteenth century (see John Wesley's letter to Law about mysticism), but his *Serious Call* exercised a profound influence at the time (especially on Samuel Johnson and John Wesley) and is still considered a classic work on the Christian life.

## LAWS, SCIENTIFIC

On the standard picture there are three kinds of facts. Some facts cannot have been otherwise. These facts include the conceptual truths (e.g., the fact that Rebecca is taller than Abe if Abe is shorter than Rebecca) and the mathematical truths (e.g., that  $2 + 1 = 3$ ). The remaining facts (i.e., the "contingent" ones) are divided between the other two classes: (1) the laws of nature (and their contingent logical consequences), such as the fact that all copper objects are electrically conductive, and (2) the "accidents," such as the fact that Jones has ten fingers and the fact (one can suppose it is a fact, though humanity

may never discover it) that there never exists a solid gold cube larger than a cubic mile.

It is widely believed that one of science's chief goals is to discover the laws of nature. Philosophers have studied the role that the concept of natural law plays in scientific reasoning.

#### LAWS VERSUS ACCIDENTS: NECESSITY AND COUNTERFACTUALS

An accident just happens to obtain. A gold cube larger than a cubic mile could have formed, but the proper conditions for it to have done so happened never to arise. In contrast, it is no accident that an electrically insulating copper object never formed, since the natural laws prohibit such a thing. In short, events must conform to the laws of nature—the laws have a kind of necessity—whereas accidents are mere coincidences. The kind of necessity characteristic of laws (and their logical consequences) is usually called *nomio* or *physical* necessity to distinguish it from various stronger varieties of necessity (such as logical, conceptual, and metaphysical necessity) possessed by various facts that cannot have been otherwise.

Had Bill Gates wanted to build a large gold cube, then there would have been a gold cube exceeding one cubic mile. But even if Gates had wanted to build an electrically insulating copper object, all copper objects would still have been electrically conductive, since events are obliged to conform to the natural laws. In other words the laws govern not only what actually happens but also what would have happened under various circumstances that did not actually happen. The laws support *counterfactuals* (i.e., facts expressed by statements of the form “Had p been the case, then q would have been the case”). Consequently, scientists use the laws to ascertain, for example, the conditions that would have prevailed on Earth had Earth been ten times nearer to the Sun. The laws are preserved under this counterfactual supposition. In contrast, an accident would not still have held, had p been the case, for some p that is *nomically possible* (i.e., consistent with all the laws' logical consequences).

Counterfactuals are notoriously context sensitive. For example, when one is emphasizing how baseball pitching talent has declined over the years, one might correctly remark that were Babe Ruth playing in the major leagues today, he would hit an astounding 120 home runs in a single season. But in a different context, one might correctly remark that were the Babe playing today, he would hit only ten homers per season, since by now he would be an old man. Which facts are to be held fixed

under some counterfactual supposition, and which are allowed to vary, depends somewhat on one's interests in entertaining that supposition. But it appears that in any context, the laws would still have held under every nomic possibility. This idea is sometimes called *nomio preservation*.

#### LAWS VERSUS ACCIDENTS: EXPLANATION AND INDUCTION

Laws have an explanatory power that accidents lack. For example, a certain powder burns with yellow flames, not another color, because the powder is a sodium salt and it is a law that all sodium salts, when ignited, burn with yellow flames. The powder had to burn with yellow flames considering that it was a sodium salt. This “had-to-ness” reflects the law's necessity. In contrast, that a couple has two children is not explained by the fact that all the families on the couple's block have two children, since this fact is accidental. Were a childless couple to move onto the block, this couple would not encounter an irresistible opposing force.

One believes that it would be mere coincidence if all U.S. presidents elected in years ending in 0 died in office. Hence, one's discovery that Warren Harding (elected in 1920) died in office fails to justify raising one's confidence that whoever was elected in 1840 died in office. A candidate law is confirmed differently: That one sample of a given chemical substance melts at 383 degrees (in standard conditions) is evidence, for every unexamined sample of that substance, that its melting point is 383 degrees (under standard conditions). This difference in inductive role between laws and accidents seems related to the fact that laws, unlike accidents, express similarities among things that reflect their belonging to the same *natural kind*. The electron, the emerald, and the electromagnetic force are all natural kinds, whereas the families on a block and the gold cubes do not form natural kinds (though gold objects, cubical and otherwise, constitute a natural kind).

#### DIFFICULTIES DISTINGUISHING LAWS FROM ACCIDENTS

The previous discussion is the standard view of the scientifically relevant differences between laws and accidents. Insofar as the same claims play all these special roles, scientific reasoning apparently recognizes an important distinction here, which philosophers label as the difference between accidents and laws. (Obviously, this distinction involves what laws do rather than which facts happen to be called “laws”; Archimedes' principle of buoyancy, the

axioms of quantum mechanics, and Maxwell's equations are all laws of physics.) However, it is notoriously difficult to capture the laws' special roles precisely.

For example, suppose one tries to distinguish laws from accidents on the grounds that laws support counterfactuals differently from accidents. That a car's maximum speed on a dry, flat road is a certain function of its gas pedal's distance from the floor is not a law (since it reflects accidental features of the car's engine). Nevertheless, this function supports counterfactuals regarding the car's maximum speed had the pedal been depressed to one-half inch from the floor, though not had certain changes been made to the engine. Indeed, all gold cubes would still have been smaller than a cubic mile even if Jones had been wearing a different shirt today. Of course, there are some nomic possibilities under which the gold-cubes generalization would not still have held. But circularity threatens if one uses the concept of nomic possibility to delimit the range of counterfactual suppositions under which a fact must be preserved for that fact to qualify as a logical consequence of the laws.

Likewise, a car's pedal-speed function, despite being accidental, can apparently be confirmed inductively. Moreover, when coupled with the road's condition and the pedal's position, it can explain the car's maximum speed. So although a fact's lawhood apparently makes a difference to science, it is difficult to identify exactly what difference it makes. This problem's stubbornness has led some philosophers to suggest that it is a mistake to distinguish laws sharply from accidents. There are merely various facts, each having a range of counterfactual suppositions under which it is preserved.

#### ARE THERE LAWS OUTSIDE OF FUNDAMENTAL PHYSICS?

Some so-called laws are plainly accidents—if they are true at all. Kepler's first law of planetary motion (that planets trace elliptical orbits) presupposes that the planets' masses happen to be negligible compared to the Sun's (since otherwise, the planets would be disturbed by their mutual gravitational influences) and that no body collides with a planet, knocking it out of its orbit. Some philosophers believe that the fundamental laws of microphysics (whatever they turn out to be) are the only genuine natural laws. This opinion is sometimes prompted by the fact that all events are ultimately nothing but the outcome of microphysical processes governed by the fundamental laws.

However, along with the laws of fundamental physics there might seem to be additional laws holding inde-

pendent of the universe's microphysical details. The second law of thermodynamics, according to which the entropy of a closed system is likely to increase, seems not to reflect any peculiarities of the fundamental forces governing the universe's ultimate constituents; even if gravity had been twice as strong as it actually is, for example, the perfume molecules from a recently opened bottle would be more likely to spread quickly throughout the room than to remain in the bottle. Likewise, the principle of natural selection, according to which fitter traits are more likely to increase their prevalence in a closed population, seems like it would still hold whatever the laws of fundamental physics might have been.

Additionally, the second law of thermodynamics appears to require that certain initial microconditions be rare—for example, that the perfume molecules within recently opened bottles not usually be arranged so that whenever one molecule threatens to escape from the bottle, another happens to come along and knock it back inside. That the perfume molecules in recently opened bottles are indeed not so coordinated would seem to be an accident rather than a nomic necessity. Accordingly, perhaps the second law is not a law at all.

The principle of natural selection is perhaps also not a law, but a conceptual truth. That a trait is "fitter" in a given environment may simply mean that it is more likely to become increasingly common in subsequent generations. Nevertheless, both the second law of thermodynamics and the principle of natural selection appear to undergo inductive confirmation, to support counterfactuals, and to explain events in the manner of natural laws.

#### LAWS OF INEXACT SCIENCES: THE PROBLEM OF *CETERIS PARIBUS*

A "special" or "inexact" science (such as anatomy, ballistics, ecology, economics, marketing, or psychology) might appear to seek (or perhaps even to have already found) facts that in these sciences play the various roles characteristic of laws. However, there are three main obstacles to regarding Boyle's law (that the product of a gas's pressure  $P$  and its volume  $V$  is constant) as a law of gases, to regarding Gresham's law (that agents hoard sound money and spend currency of more dubious value) as a law of economics, or to regarding the area law (that larger islands have greater biodiversity) as a law of island biogeography. Each of these obstacles has persuaded some philosophers to deny that inexact sciences have laws.

First, any such "law" comes with a *ceteris paribus* qualification. Though *ceteris paribus* means roughly "all

other things being equal,” a given qualification may be better captured as the idea that the specified correlation holds “normally,” “in the ideal case,” “in the absence of disturbing factors,” or as long as certain other factors have certain values. The law is “hedged” in some way. For example, the gas in a container departs significantly from Boyle’s law when its temperature is changed, some of the gas escapes, or the pressure is high. These circumstances are ruled out by the *ceteris paribus* proviso to Boyle’s law. But what exactly does “PV is constant, *ceteris paribus*” mean?

If it means that PV is constant unless it is not, then the “law” is a trivial, noncontingent truth rather than an interesting discovery. If instead *ceteris paribus* is shorthand for a list of every factor allowed by fundamental microphysics and able to cause a gas’s PV to vary, then Robert Boyle could not have discovered his law, since he did not know some of these factors (e.g., gas molecules adhering to the container’s walls or attracting one another). Alternatively, some philosophers contend that Boyle’s law describes only fictitious “ideal gases” that lack any interfering factors. But then it is unclear how observations of actual gases could confirm Boyle’s law or how knowledge of Boyle’s law could justify scientists in using it to predict the behavior of actual gases. Boyle had neither the concept of an ideal gas nor an account of what makes a gas ideal (e.g., that it consists of molecules without mutual attraction and occupying no finite volume). Such an account is not part of Boyle’s law. Rather, the extent to which an actual gas has constant PV is explained by the extent to which it resembles an ideal gas.

Apparently then, *ceteris paribus* in Boyle’s law refers only to the disturbing factors of which Boyle was aware (high pressure, changes to the gas’s temperature, and so forth). There may be no complete list of these factors. Obviously (to shift examples), Gresham’s law does not apply if the society is wiped out, if its members believe that hoarding the sounder currency causes illness, and so forth. Part of understanding Gresham’s law is knowing how to recognize whether some factor qualifies as disturbing. One can catch on to which factors these are without having to read a complete list of them. (Nonexperts may even [in an attenuated sense] understand the *ceteris paribus* proviso without being able to tell themselves whether some factor qualifies as disturbing, just as they understand other technical terms: by virtue of knowing who the relevant experts are to whom they should defer.)

## LAWS OF INEXACT SCIENCES: THE PROBLEM OF TRUTH

However, societal events are ultimately nothing but the outcomes of microphysical processes. Certain sequences of microevents permitted by the fundamental laws of physics involve a society’s members hoarding the weaker currency and spending the sounder. In one such sequence each member of the society happens whenever he or she spends money to forget momentarily which currency is sounder, because as chance would have it, some neuron in each agent’s brain behaves at that moment in a manner that the fundamental microlaws deem extremely unlikely, but nevertheless possible. The *ceteris paribus* proviso to Gresham’s law does not rule out this freakish sequence of events, since economists surely do not need to grasp the subtleties of fundamental microphysics to understand the proviso to Gresham’s law.

In other words, not all exceptions to a macrolevel “law” can be specified in the vocabulary of the macroscience. For example, it might require physics (or at least neurology) to specify certain circumstance in which an agent would depart from a psychological “law.” The *ceteris paribus* proviso fails to cover those exceptions.

This is the second obstacle to regarding inexact sciences as having genuine laws: The alleged laws are false or, if true, merely accidentally so. Perhaps, however, one should relax the requirement that genuine laws be exceptionless in favor of holding that a law be sufficiently accurate for the relevant purposes. The proviso to Boyle’s law neglects to mention a host of petty influences that make the PV of actual gases vary somewhat. Still, Boyle’s law with its proviso (which rules out the major interfering factors—the ones that scientists cannot afford to neglect) is often enough close enough to the truth for various purposes in chemistry, theoretical and practical. Fully understanding Boyle’s law requires knowing the range of purposes for which it can safely be applied. Likewise, the freakish sequence of neural events mentioned earlier is too rare to make Gresham’s law unreliable for the purposes of economics.

The limited range of a special science’s interests influence which facts qualify as laws of that science. Consider another example: The human aorta carries all the body’s oxygenated blood from the heart to the systemic circulation. This reference to “the human aorta” (a generic), rather than to all or to most human aortas, apparently indicates that one is dealing here with a policy of drawing influences that, although fallible, is sufficiently reliable for certain purposes—in this case for forming expectations about medical patients in the

absence of more specific information regarding them. In human medicine this fact about the human aorta apparently functions as a law in connection with counterfactuals, explanations, and inductions. However, this aorta fact is merely an accident of natural history; it might not have held had evolutionary history taken a different path. Still, medicine does not treat evolutionary history as a variable. A physician might say that the shooting victim would not have survived even if he or she had been brought to the hospital sooner, since the bullet punctured his or her aorta and the human aorta carries all the body's oxygenated blood from the heart to the systemic circulation. (This aorta fact would still have held had the victim been brought to the hospital sooner.) But it would not be medically relevant to point out that the victim might have survived had evolutionary history taken a different course. Accordingly, that the human aorta carries all the body's oxygenated blood to the systemic circulation may be a law of human physiology even if it is an accident of physics.

#### LAW OF INEXACT SCIENCES: THE PROBLEM OF NECESSITY

But (to shift examples) even if the law that larger islands have greater biodiversity (all other things—such as their distance from the mainland—being equal) is sufficiently reliable for the purposes of island biogeography, what makes this fact an island-biogeographical law? What makes it necessary? This is the third obstacle to inexact sciences having genuine laws of their own—that is, to their being autonomous.

Recall *nommic preservation*: that the laws would still have held under any counterfactual supposition that is logically consistent with every law. There appears to be no set of truths that is closed under logical consequence and that contains accidents (except the set of all truths) where every member of the set would still have been true under every counterfactual supposition that is logically consistent with every member of the set. Accordingly, it has been suggested that a truth *n* is a nomic necessity exactly when *n* belongs to a stable set, where a set is stable exactly when it includes every logical consequence of its members, it does not contain every truth, and its members are not only true but also all preserved under as broad a range of counterfactual suppositions as they could all logically possibly be—namely, under every supposition that is logically consistent with every member. On this view necessity involves possessing maximal invariance under counterfactual perturbations. No necessity is possessed by an accident, even one (such as a car's pedal-speed

function) that would still have held under many counterfactual suppositions. (The set consisting of a car's pedal-speed function, with its logical consequences, is unstable since its members would not all still have held under engine alterations with which the pedal-speed function is logically consistent.) Stability allows one to draw a sharp distinction between laws and accidents. It also gives one a way to escape the circle involved in specifying the nomic necessities as the truths that would still have held under every nomic possibility.

This conception of nomic necessity can easily be relativized to particular sciences. Perhaps the area law belongs to a set of claims that are all sufficiently reliable for the purposes of island biogeography, where the set does not contain all such claims and where its members would all still have been sufficiently reliable under any counterfactual supposition that is not only consistent with all of them being reliable but also relevant to island biogeography. In that case the set's members are collectively as resilient under counterfactual suppositions relevant to island biogeography as they collectively could be. Therefore, they possess nomic necessity for island biogeography.

On this view a special science's laws need not include every detail of the fundamental microphysical laws. For example, biological species would still have been distributed according to the laws of island biogeography (if there are any such laws) even if creatures were made of a continuous rigid substance rather than molecules, contrary to microphysical laws. Whether a given special science is autonomous remains for scientific research to discover. Whether the fundamental microphysical laws are privileged among the natural laws (e.g., in having greater generality or being strictly true) remains philosophically controversial.

## LAWS OF NATURE

The "laws of nature" are the general ways of working of the physical and mental world. Many natural scientists have as one of their great aims the uncovering of these laws. The topic of laws of nature has been the subject of

vigorous discussion in contemporary philosophy. Three broad tendencies have emerged, with a number of important variations within these tendencies.

### THE REGULARITY OR HUMEAN VIEW

Since the work of David Hume, at least, there have been many philosophers, particularly those in the empiricist tradition, who have tried to analyze both causes and laws (which they tend not to distinguish very clearly) in terms of mere regular successions or other regularities in the behavior of things. Laws tell us that, given a phenomenon of a certain sort, then a further phenomenon of a certain sort must occur in a certain relation to the first phenomenon. Particularly since the rise of quantum physics, this may be modified by saying that there must be a certain probability that the further phenomenon will occur. Regularity theorists see this "must" as mere universality: This is what always happens.

A great many difficulties have been raised against this position (for a fairly full listing see Armstrong 1983, pt. 1). The most important of these are as follows.

1. The intuitive difference between merely accidental uniformities and nomic (lawlike) uniformities. The traditional example is the contrast between the accidental uniformity that every sphere of gold has a diameter of less than one mile and the nomic uniformity that every sphere of uranium 235 has a diameter of less than one mile, because that diameter would ensure "critical mass" and the explosion of the sphere.
2. Laws of nature "sustain counterfactuals." If it is a law that arsenic is poisonous, then if, contrary to the facts, you had drunk arsenic, you would have been very sick. But from the fact that no human being of Neanderthal race ever spoke English, it by no means follows that if, contrary to fact, some of them had lived in an English-speaking society, they would not have spoken English. The uniformity that Neanderthals spoke no English does not sustain counterfactuals.
3. A regularity theorist cannot give a satisfactory solution to the problem of induction. If laws are mere regularities, what rational grounds have we for believing that observed uniformities will continue to hold in the future and for the unobserved generally?
4. A regularity theorist is likely to identify merely probabilistic laws with actually occurring frequencies. This identification is difficult, because

such laws do not actually rule out distributions with the “wrong” frequencies. All that probabilistic laws do is to make such frequencies improbable; they do not make them nomically impossible.

5. Science admits certain laws that may well have no positive instances falling under them. The most famous example is Isaac Newton’s first law of motion. An uninstantiated law would have to be a vacuous uniformity, but there are far too many such uniformities all to be laws.

Those who continue to work in the regularity tradition try to meet these and other difficulties largely by distinguishing “good” uniformities that deserve to be called laws and “bad” ones that do not. There are two main approaches, the epistemic and the systematic.

Epistemic theorists emphasize the nature of the evidence that we have for claiming that certain uniformities obtain. References and criticism may be found in W. A. Suchting (1974), G. Molnar (1974), Fred Dretske (1977), and David M. Armstrong (1983). Brian Skyrms’s (1980) resiliency account is a sophisticated epistemic approach. His basic idea is that we give assent to a generalization, and count it lawlike, only if we find it to hold under a wide variety of circumstances and conditions. For criticism of Skyrms, see Michael Tooley (1987) and J. Carroll (1990).

The systematic approach has been championed by David Lewis, explicitly basing himself on a suggestion made by F. P. Ramsey. Lewis says that “contingent generalization is a *law of nature* if and only if it appears as a theorem (or axiom) in each of the true deductive systems that achieves the best combination of simplicity and strength” (1973, p. 73). Further discussion may be found in Lewis (1986). He himself finds that his greatest difficulties are associated with probabilistic laws. For criticism of Lewis see Armstrong (1983), Tooley (1987), and Carroll (1990).

## STRONG LAWS

One who judges that no regularity theory of laws can succeed may wish to argue that laws are something stronger than mere uniformities or statistical distributions. Laws may be called strong if their existence entails the existence of the corresponding uniformities and so on but the reverse entailment fails to hold.

Traditional theories of strong laws tended to see these laws as holding necessarily. Given all the antecedent conditions, the consequent is entailed. In the days when Euclidean geometry was unchallenged, geometrical mod-

els were attractive. As with geometrical theorems, this necessity was thought to be discoverable, at least potentially, a priori. Granted that laws might in practice be discovered by experience, just as the Pythagorean theorem might be discovered by measuring and adding areas, it was still thought that a sufficiently powerful intellect might spell out the necessity involved without the aid of experience. This approach seems to have been abandoned by contemporary philosophers (though there are hints in Martin 1993). It now seems agreed, in general, and in agreement with regularity theorists, that the laws of nature can be discovered only a posteriori.

Upholders of strong laws do, however, differ among themselves whether these laws are contingent or necessary. The contingency view (also held by regularity theorists) is represented by Dretske (1977), Tooley (1977, 1987) and Armstrong (1983). These three evolved their rather similar views independently and almost simultaneously. Laws are argued to be dyadic relations of necessitation holding contingently between universals, schematically  $N(F,G)$ . Such a relation entails the regularity that all Fs are Gs, but the regularity does not entail  $N(F,G)$ . Dretske presents the central idea with particular clarity; Tooley and Armstrong develop the theory more fully. Tooley argues that the possibility of certain sorts of uninstantiated laws demands uninstantiated universals, leading him to what he calls a factual Platonism about universals. Armstrong, however, tries to get along with instantiated universals only.

The theory appears to be able to handle probabilistic laws (see Armstrong 1983, chap. 9; Tooley 1987, chap. 4). The connection between universals envisaged by the theory may be thought of as involving connections of differing strength holding between antecedent and consequent universals. The greatest strength, one (exactly one, not one minus an infinitesimal), represents the probability involved in an old-style deterministic law. The consequent universal must be instantiated if the antecedent universal is. Numbers between nought and one give the lesser probability of the consequent being instantiated under these conditions. This probability is an objective one. The antecedent universal, if instantiated, bestows an objective propensity, as some say, for the instantiation of the consequent.

An obvious cost of this sort of theory is that it must postulate universals. This is a stumbling block to many. But by far the most important criticism of this account has been developed by Bas van Fraassen (1989, chap. 5; see also the discussion-review of this book by him, Earman, Cartwright, and Armstrong 1993). He poses two

difficulties: the identification problem and the inference problem. The first is the problem of identifying in a non-circular way the nature of the necessitation relation supposed to hold between the universals involved in the law. The second is the problem, given a concrete account of this relation, of understanding why it is legitimate to infer from the fact that the universals are so related to the existence of corresponding uniformities or frequencies in the world. Van Fraassen argues that solving the one problem makes it impossible to solve the other. A clear account of the relation makes the inference problematic; a clearly valid inference makes the relation no more than something that validates the inference.

The view that laws of nature are necessities discovered a posteriori is developed by Sydney Shoemaker (1984) and Chris Swoyer (1982). They build on Saul Kripke's (1980) arguments for a posteriori knowledge of necessity, and Kripke hints that laws of nature may have this status. Their view depends upon taking a different view of properties from that found in Dretske, Tooley, and Armstrong. For the latter, properties are conceived of as "categorical" or self-contained entities. But for Shoemaker and Swoyer, properties, either singly or in combination, are nothing apart from the laws they enter into. They might be described as pure powers or dispositions to produce law-governed consequences.

On this view, therefore, if it is a law that property F ensures possession of property G, then it is the very essence of F so to ensure G, and so the law is necessary. That there are things having property F is contingent, but that F ensures G is necessary. It seems, then, that the dispute between contingent strong laws and necessary ones depends on the true theory of properties. See Richard Swinburne's (1983) critical comments on Shoemaker.

The view of properties just discussed might be called dispositionalism as opposed to categoricism. There are theorists who favor a view of properties that gives them both a categorical and a dispositional (or power) side; see Evan Fales (1990) and C. B. Martin (1993). It is to be noted that both in pure dispositionalism and this mixed theory there is a strong tendency to regard laws as not fundamental but rather analyzable in terms of causal relations holding between individual events and particulars (singular causation). These causal relations, and so their laws, are determined by the nature of the dispositions or powers that particulars have.

## ELIMINATIVISM ABOUT LAWS

The regularity theory of laws is a deflationary theory. It holds that there is less to being a law than one might nat-

urally think. It also faces a number of serious difficulties. One response, rather typical of our age, is to meet the difficulties, not by proposing a strengthened theory of laws, but by taking the deflation further and arguing that there are no such things as laws. This is the position taken by van Fraassen in *Laws and Symmetry* (1989). A natural comparison is with eliminative materialism, which denies the existence of the mind in favor of the brain.

Van Fraassen begins with a systematic criticism, first of Lewis's version of the regularity theory, and then of various strong views. The rejection of laws he links to his "constructive empiricism," according to which the aim of science is not truth in general but only empirical adequacy, defined as truth with respect to what is observed. Beyond the observable, all that can usefully be done is the constructing of models that are in a deep way adequate to the phenomena and that may be true but about which we can have no special reason to think them true. In these constructions considerations of symmetry play an energizing role.

A certain skepticism about laws is also to be found in Nancy Cartwright's *How the Laws of Physics Lie* (1983). Her skepticism concerns the fundamental as opposed to more messy phenomenological laws. The former may explain better, but the latter are truer to the facts! The distinction she is concerned with is one made by physicists, and the "phenomenological" laws go far beyond van Fraassen's observables. Cartwright accepts these laws because the entities they deal with, though perhaps unobserved, appear to exist and to act as causes. In *Nature's Capacities and Their Measurement* (1989), she argues that the world is a world of singular causes, individual entities interacting with each other. The nature of these interactions is determined by the capacities of these entities. Her capacities seem close to the dispositions and powers that contemporary necessitarians identify with properties.

## LAW OF NATURE [ADDENDUM]

Since David M. Armstrong's entry was first published in 1996, the philosophical debates he identifies have evolved in minor ways. There is still the central debate between the Humeans (the regularity theorists) and the anti-Humeans (the proponents of strong laws), and there are still those who choose to deny that there are any laws, to be eliminativists, rather than engage in the central debate.

This addendum indicates how the literature has shifted focus to questions surrounding supervenience and whether laws govern. It also engages in a fuller discussion of the relationship between laws of nature and epistemological issues, including the role of laws in inductive inference and some skeptical challenges for both Humeans and anti-Humeans.

### SUPERVENIENCE

The persevering Humean theory of laws is the systematic approach made popular by David Lewis and described briefly by Armstrong. (Versions of this account are also defended in Earman [1984] and in Loewer [1996].) A feature of this view prized by its supporters is its consistency with Humean supervenience, a thesis formulated various ways (see Earman and Roberts, 2005, Part I) but that basically maintains that the most fundamental nonmodal features of a universe fix everything else about it, including what its laws of nature are. Some anti-Humeans, the ones who think that laws are metaphysical necessities (e.g., Bigelow, Ellis, and Lierse 1992) accept that the laws do supervene for the mere reason that metaphysical necessities hold no matter what. But most anti-Humeans, the ones who believe that it is a contingent matter of fact whether something is a law, think that what the laws are does not supervene.

Michael Tooley (1977) asks one to suppose that there are exactly ten different kinds of fundamental particles. So, there are fifty-five possible kinds of two-particle interactions. Suppose also that fifty-four of these kinds of interactions have been studied and fifty-four laws have been proposed and thoroughly tested. It just so happens that there are no interactions between the last two kinds of particles ever. These final two kinds of particles are arbitrarily labeled as X and Y particles. What is interesting about this example is that it seems that many different X-Y interaction laws are consistent with all the events that take place: There might be a law that, when X and Y particles interact, the particles are destroyed; but instead there might be a law that, when X and Y particles interact, the particles bond.

Tooley's example presents a problem for Humeans. Consider what a certain, simple, regularity account would say about the seeming possibility that it is a law in the ten-particle world that when X and Y particles interact they bond. The account holds that P is a law of nature if and only if P is a true, contingent, universal generalization. It implies the absurdity that both of the X-Y regularities mentioned earlier are laws. This is absurd because such annihilation and bonding events are incompatible. The

account fails to pick out the bonding regularity as the law because the concepts invoked do not differentiate between bonding and annihilation. Because the two X-Y regularities are both true, contingent, universal generalizations, they both get counted as laws. *Prima facie*, Lewis's more sophisticated account is faced with the same problem. Not only do the two key X-Y regularities not differ regarding their truth, their contingency, or their logical form, they also do not differ regarding their simplicity or their strength. So, arguably, either these two regularities would both belong to all the true deductive systems with a best combination of simplicity and strength or else neither of them would.

Eliminativists may acknowledge the intuitiveness of Tooley's example but may see that as reason to think there are no laws. There is also a certain nonstandard way of being Humean that sidesteps the issue in something of a similar fashion. Barry Ward, in "Humeanism without Humean Supervenience: A Projectivist Account of Laws and Possibilities" (2002), maintains that lawhood sentences are not fact-stating, that they serve a different role, one of projecting some noncognitive attitude.

## DO LAWS GOVERN?

The standard approach for Humeans is to somehow deny that Tooley's example and other cases to the same effect (see Carroll 1994, pp. 57–85) are genuinely possible. They hold that the intuition that the lawfulness of each of the two X-Y interaction principles is consistent with the events of the ten-particle world is somehow misleading or ill founded. Helen Beebe, in "The Non-governing Conception of Laws of Nature" (2000), suggests that the source of the intuition is a certain veneration of a conception of laws that holds that laws govern the course of history (also see Loewer 1996, pp. 115–117). The idea is that, if one comes to the debate with the governing conception in mind, one is likely to find nonsupervenience examples convincing, but using this conception to reject Humean analyses of lawhood is to beg the question because it is a conception Humeans reject. Having their own conception of laws not as governing but as summarizing, Humeans insist that at most one of the two X-Y interaction laws is consistent with the events of the ten-particle world. Anti-Humeans are sometimes accused of relying on a nonscientific or even theistic or legalistic conception of what it is to be a law, though the anti-Humeans themselves will insist, on the contrary, that it is their conception that is the scientific conception and that it needs no theistic or legalistic underpinning. Nevertheless, one idiosyncratic anti-Humean, John Foster, in *The*

*Divine Lawmaker: Lectures on Induction, Laws of Nature, and the Existence of God* (2004), provides fuel for the Humean fire by arguing that lawful regularities ultimately must be explained in terms of the agency of God.

## LAWS AND INDUCTION

In "The New Riddle of Induction" (1983) Nelson Goodman argues that the difference between laws of nature and accidental uniformities is linked with the problem of induction via the concept of lawlikeness. Lawlikeness is whatever additional characteristic a universal generalization needs, aside from truth, to be a law. Goodman claims that, if a true generalization is accidentally true (and so not lawlike), then an instance of the generalization does not confirm the generalization.

There are examples that threaten Goodman's contention. Suppose a brand new die will be thrown twice and then destroyed. Also suppose that one is interested in whether it will come up six both times it is tossed. It is thrown the first time and it does land six. Notice that this single instance has increased dramatically the probability that all tosses of this die will land six. Before the first toss, that probability was one out of thirty-six. Now that the first toss has landed six, that probability has gone up to one-sixth. So, apparently, Goodman's claim is mistaken; observation of one instance of the generalization that every toss of this die will land six has provided confirmation even though the generalization is not lawlike.

One natural response to this kind of example maintains that probability raising is not the notion of confirmation that Goodman had in mind. The temptation is to hold instead that a generalization is lawlike if observed instances confirm that the generalization also holds for unexamined cases. (Notice that, in the die example, the first roll landing six does not raise the probability that the second roll will land six.) But this alternative is not right either. Maybe you know that Sam sorts his coins by putting nickels in one pocket, dimes in another, and so on; he is fanatical that way. You do not know, however, which pocket he keeps his nickels in. Sam shows you one of the coins from his left-front pocket and you see that it is a nickel. Evidently this instance of the generalization that all the coins in Sam's left-front pocket are nickels has confirmed that all the coins in this pocket are nickels. Given your background knowledge, you seem perfectly justified in believing that the generalization is true even though it is not lawlike. You also have reason to believe that the other coins in his left-front pocket, the ones you have not examined, are nickels.

Followers of Goodman have their work cut out for them. The biggest obstacle involves background beliefs, as is evidenced by the two examples just given where prior knowledge that the die would only be tossed twice and prior knowledge of Sam's fanatical coin sorting played a major role. Here is the basic problem: The confirmation of a generalization or its unexamined instances is sensitive to the background assumptions in place. So much so, that with assumptions of the right sort, just about anything can be confirmed irrespective of its lawlikeness. Elliot Sober's "Confirmation and Law-likeness" (1988) presents a series of difficult cases and concludes by expressing this concern about background assumptions. Marc Lange's *Natural Laws in Scientific Practice* (2000, pp. 111–142) takes up the challenge, in part, by further refining the relevant notion of confirmation, characterizing what he takes to be an intuitive notion of inductive confirmation, and arguing that only those generalizations that are not believed not to be lawlike can be inductively confirmed.

#### A SKEPTICAL CHALLENGE FOR HUMEANS

Sometimes the idea that laws have a special role to play in induction serves as the starting point for an anti-Humean criticism of Humean analyses. Fred I. Dretske (1977, pp. 261–262) and Armstrong (1983, pp. 52–59) adopt a view according to which induction involves an inference to the best explanation (also see Foster 2004). On its simplest construal, the view describes a pattern that begins with an observation of instances of a generalization, includes an inference to the corresponding law (this is the inference to the best explanation), and concludes with an inference to the regularity itself or to some conclusion about its unexamined instances. The complaint lodged against Humeans is that, on their view of what laws are, laws are not suited to explain their instances and so cannot sustain the required inference to the best explanation. After all, if laws are summaries of their instances, then they cannot explain their instances. Does the fact that all Fs are Gs explain why this F is a G? It is hard to see how it could; that this F is G is part of what makes it true that all Fs are Gs.

#### A SKEPTICAL CHALLENGE FOR ANTI-HUMEANS

Sometimes very different skeptical considerations are used by Humeans against the anti-Humeans. Prompted by examples like Tooley's, it can seem that the events of the actual world fail to determine what the laws are. Sci-

entists and philosophers believe it is a law that all signals have speeds less than the speed of light, but if the course of our actual history is consistent with this generalization not being a law, with it being a remarkable coincidence, then can anyone really know that it is a law of nature?

John Earman and John Roberts formalize this kind of reasoning in "Contact with the Nomic: A Challenge for Deniers of Humean Supervenience about Laws of Nature (Part II): The Epistemological Argument for Humean Supervenience" (2005). Let T be a theory that posits at least one law. Label one of the laws L and reformulate the theory as the conjunction that L is a law of nature and X. (So, X is the rest of the theory aside from the part that posits L as a law.) Let T\* be the theory that L is true, not a law of nature, and X. So, T and T\* cannot both be true; they differ on whether L is a law, though they agree on L's truth. Then, the argument is straightforward:

- (1) If Humean supervenience is false, then no empirical evidence can favor T or T\* over the other
- (2) If no empirical evidence can favor T or T\* over the other, then one cannot be epistemically justified in believing that T is true
- (3) If Humean supervenience is false, one cannot be epistemically justified in believing that T is true

Earman and Roberts make no assumptions about T other than that it takes something to be a law. So, if Earman and Roberts's argument is sound and Humean supervenience is false, then no one is justified in believing that any proposition is a law. It is only a short step from there to the conclusion that no one knows what any of the laws are. As Earman and Roberts deny skepticism about laws, they ultimately see this as an argument for Humean supervenience.

In response, the anti-Humean will appeal to the history of philosophy, citing instances of epistemological questions that have befuddled metaphysical issues. George Berkeley's idealism is a dramatic example. Faced with René Descartes's skeptical investigations, Berkeley advanced the untenable metaphysical position according to which material objects are nothing more than collections of ideas. So, Humeans have to make it clear that they are not making a mistake parallel to the one made by Berkeley. Also, it is important to remember that, in some sense, it could be that nobody knows what the laws are; it is obvious that there are a great many ways that our world could be such that scientists will not discover every fact, and so our world could be such that no one will discover any of the laws.

Nevertheless, Humeans and anti-Humeans alike are right to balk at a conclusion to the effect that we can never know what the laws are. If a philosophical position on lawhood, be it the identification of laws with regularities or the denial of Humean supervenience or something else, has the consequence that no one ever knows anything to be a law, then the defender of that position should be concerned. Part of the motivation for engaging in a philosophical investigation of laws is the seeming truism that science has as one of its aims to uncover the laws. If it should turn out that science is bound not to result in knowledge of the laws, then philosophy would have led us to at least a disturbing take on the nature of the world.

## LAWS OF THOUGHT

The term "laws of thought" traditionally covered the principles of identity, of contradiction, of excluded middle, and occasionally the principle of sufficient reason. Whereas these principles were frequently discussed from the time of the Greeks until the beginning of the twentieth century, the term has become obsolete, for at least two good reasons. One is the great and confusing variety of meanings with which it has been used, the other is the now generally acknowledged fact that no viable system of logic can be constructed in which the principles of identity, contradiction, and excluded middle would be the only axioms. Typical discussions of these principles are to be found, for example, in Friedrich Ueberweg's *System der Logik* and in H. W. B. Joseph's *Introduction to Logic*. In the following discussion the principle of sufficient reason, which, unlike the others, cannot be interpreted as a principle of formal logic, will not be dealt with.

The three laws of thought have in the main been conceived of as descriptive, prescriptive, or formal. As *descriptive* laws, they have been regarded as descriptive (a) of the nature of "being as such," (b) of the subject matter common to all sciences, or (c) of the activity of thinking or reasoning. As *prescriptive* laws, they have been conceived of as expressing absolute or conventional standards of correct thinking or reasoning. As *formal* laws, they have been held to be propositions which are true in virtue of their form and independently of their content, true *in* all possible worlds, or true *of* any objects whatsoever, whether these objects exist or not. Distinctions between these conceptions are often blurred, since they depend on implicit and often unclear assumptions about the relations between factual, normative, and metaphysical propositions: It is, for example, rarely investigated either to what extent various kinds of rules depend for their satisfiability on what is the case or to what extent logic is or can be free from metaphysical presuppositions or implications.

All these very different conceptions of the laws of thought are compatible with their traditional formulations, which lack the precision now achievable by means of the axiomatization and formalization of theories. Examples of typical, traditional formulations are: For the law of identity,  $A$  is  $A$ ; everything is what it is; every subject is its own predicate. For the law of contradiction,  $A$  is not not- $A$ ; judgments contradictorily opposed to each other cannot both be true. For the law of excluded middle, everything is either  $A$  or not- $A$ ; judgments opposed as contradictories cannot both be false, nor can they admit the truth of a third or middle judgment, but one or the other must be true, and the truth of the one follows from the falsehood of the other. An obvious ambiguity concerning the law of identity is connected with the question whether *is* is to be taken as expressing equality or as the copula between subject and predicate, and, in the latter case, whether or not it implies the existence of the subject. Again, the term *not* admits of different interpretations according to different metaphysical and logical assumptions about negation.

## DESCRIPTIVE INTERPRETATIONS

**METAPHYSICAL INTERPRETATION.** For Aristotle, who discussed the laws of thought in his logical and metaphysical works, they are primarily descriptive of being as such and only secondarily standards of correct thinking. It is thus a metaphysical or ontological impossibility that “the same can and cannot belong to the same in the same reference” (*Metaphysics* III, 2, 2), from which it follows as a rule of correct thought and speech that it is incorrect to assert that “the same is and is not” (*Metaphysics* IV, 6, 12). Aristotle produced seven “proofs” to demonstrate the indispensability of the law of contradiction. With a similar intention, formal logicians are nowadays wont to show that its negation implies any proposition whatever (and thus also the law of contradiction itself) by some such reasoning as the following: (1) To assume that the law of contradiction is false is to assume for some proposition  $p$  that  $p$  and not- $p$  are both true. (2) From the truth of  $p$  it follows that “ $p$  or  $x$ ” is also true, where  $x$  is an arbitrary proposition and “or” is used in the nonexclusive sense of “and/or.” (3) From the truth of “ $p$  or  $x$ ” and the truth of not- $p$  the truth of  $x$  follows. But  $x$  is an arbitrary proposition for which, for example, the law of contradiction may be chosen.

Aristotle’s defense of the law of contradiction as descriptive of “being as such” includes implicitly a defense of the metaphysical principle of identity against Heraclitus, who held it possible for the same thing to be

and not to be and who explained the concept of becoming as implying the falsehood of the principle that everything is what it is. Before Aristotle this metaphysical principle had been defended by Parmenides.

Aristotle’s arguments for the truth of the principle of excluded middle are again metaphysical. They are connected with his rejection of the Platonic doctrine that attempts to mediate between Heraclitus and Parmenides. The changing sensible and material objects, which in Plato’s phrase “tumble about between being and nonbeing,” are placed by Plato between the eternal Forms, which fully and truly exist, and that which does not exist at all, that is, they are “a third” between being and nonbeing. The metaphysical principle of excluded middle, as understood by Aristotle, excludes any such third. This principle has sometimes been taken to imply fatalism: Since of any two contradictory statements one must be true, of any two contradictory statements about the future one must be true, so that, it is argued, the future is wholly determined. In a famous passage about “the sea fight tomorrow” Aristotle refutes this argument: It is, he points out, necessary that the sea fight will or will not take place tomorrow. But it is not true that it will *necessarily* take place tomorrow or *necessarily* not take place tomorrow. Indeed the logical necessity of a disjunction “ $p$  or not- $p$ ” does not imply that either  $p$  or not- $p$  is a necessary proposition.

**METAPHYSICAL REFUTATION.** Heraclitus, Parmenides, Plato, and Aristotle conceived of the laws of thought as controversial metaphysical principles, and just as Aristotle attempted their justification on metaphysical grounds, so did G. W. F. Hegel, Karl Marx, and Friedrich Engels attempt their refutation on metaphysical grounds. Hegel’s attack was based on his distinction between abstract understanding, which petrifies and thus misdescribes the ever-changing “dialectical” process that is reality, and reason, which apprehends its true nature. Hegel objected to the principle that  $A$  is  $A$  or, what for him amounts to the same thing, that  $A$  cannot at the same time be  $A$  and not- $A$  because “no mind thinks or forms conceptions or speaks in accordance with this law, and ... no existence of any kind whatever conforms to it” (*Die Encyclopädie der philosophischen Wissenschaften*). For Hegel contradiction is not a relation that holds merely between propositions but one which is also exemplified in the real world, for example, in such phenomena as the polarity of magnetism, the antithesis between organic and inorganic matter, and even the complementarity of complementary colors. With such an interpretation it becomes possible for him to assert that “contradiction is the very moving principle

of the world” and that “it is ridiculous to say that contradiction is unthinkable.” Aristotle’s metaphysics corresponds to a logic in which the metaphysical principles of identity, contradiction, and excluded middle have their logical counterpart in corresponding laws of reasoning. The counterpart of Hegel’s rejection of these metaphysical principles is not any traditional logical theory but a “dialectical” logic, or dialectics.

The Hegelian point of view was adopted by Marx and Engels with the difference that they conceived reality not as ideal but as material. Engels, unlike Hegel, did not even acknowledge the law of identity as valid for the abstractions of mathematics. His arguments, based on the alleged structure of the differential and integral calculus, seem—at least today—confused. He held, for example, that under certain circumstances straight lines and curves are literally identical.

**EMPIRICAL INTERPRETATION.** From the conception of the laws of thought as descriptive of “being as such,” whatever this may mean precisely, we must distinguish the conception of them as empirical generalizations of very high order. This view was most clearly expressed by John Stuart Mill in his *System of Logic* (London, 1843). Thus, he regarded the principle of contradiction as one “of our first empirical generalizations from experience” and as “originally founded on our distinction between belief and disbelief as two different mutually exclusive states” (*System of Logic*, Book II, Ch. 7). He similarly argued that the empirical character of the law of excluded middle follows from, among other things, the fact that it requires for its truth a large qualification, namely “that the predicate in any affirmative categorical proposition must be capable of being meaningfully attributed to the subject, since between the true and the false there is the third possibility of the meaningless” (Book II, ch. 7). Mill’s view must not be taken to imply that the laws of thought are psychological laws, describing the processes of thought—a view which rests on a confusion between thinking and correct thinking.

### PRESCRIPTIVE INTERPRETATIONS

**REGULATIVE INTERPRETATION.** Another interpretation of the laws of thought regards them as in some sense prescriptive—based on some absolute authority, by analogy with moral laws, or based on conventions admitting of possible alternatives, by analogy with municipal laws. Traces of the former view are, for example, still found in J. N. Keynes’s *Formal Logic*, one of the last valuable treatises on traditional formal logic. According to the preface

of this work, logic deals with the laws regulating the processes of formal reasoning purely as “regulative and authoritative” and as affording criteria for the discrimination between valid and invalid reasoning.

**CONVENTIONALIST INTERPRETATION.** Versions of the conception that all logical principles are based on conventions have rarely been worked out with sufficient care. According to A. J. Ayer’s *Language, Truth and Logic* (1936; 2nd ed., 1946) every logical principle is based on conventions. Thus “not ( $p$  and not- $p$ )” is logically necessary because the use of “and” and “not” is governed by certain linguistic conventions, which are neither true nor false. Yet given these conventions the proposition “not ( $p$  and not- $p$ ),” that is, the law of contradiction, is necessarily true. Ayer and those who have held similar views never consider the question whether, and to what extent, linguistic conventions depend on some nonconventional framework which restricts one’s freedom to formulate, accept, or reject them. Can one, for example, by adopting suitable conventions for the use of “or” and “not” really think or speak in contravention of the principle that under the usual conventions is expressed by “not ( $p$  and not- $p$ )”?

Conventionalism is most plausible when it explains the necessity of alternative systems of definitions and of alternative systems of logic as being based on conventions, in the sense of rules whose acceptance is not obligatory. In the case of the law of contradiction no alternative is conceivable, so that the “convention” on which it is based would have to be obligatory in a sense in which the other conventions are not. However, an admission of “conventions obligatory for all thinkers” would bring conventionalism much nearer to views of logic which, at least *prima facie*, it seems to reject.

### FORMAL INTERPRETATIONS

**LEIBNIZ AND KANT.** According to Gottfried Wilhelm Leibniz there are two kinds of truths, truths of fact and truths of reason, truths of reason being true in all possible worlds and therefore descriptive of facts in such a way that not even God can change them. Leibniz regarded as a necessary and sufficient condition for a truth’s being a truth of reason, and thus logically necessary, that its analysis should reveal it to depend wholly on propositions whose negation involves a contradiction, that is, on identical propositions (see, for example, *Monadology*, Secs. 31–35). He even held, in the second letter to Samuel Clarke, that the law of contradiction is “by itself sufficient” for the demonstration of “the whole of arithmetic

and geometry.” Although the thesis that all logical, as well as all mathematical, truths are demonstrable by means of the law of contradiction alone is, from the point of view of contemporary knowledge, mistaken or at least obscurely expressed, the characterization of logical truths as true in all possible worlds is still the root of the Bolzano-Tarski definition of logical validity.

Although Immanuel Kant opposed the Leibnizian doctrine that the truths of mathematics are logical truths, he adhered to the principle of contradiction as the supreme principle of all logical truths or, more precisely, as the “general and wholly sufficient principle of all analytical knowledge.” Since the truth of such knowledge in no way depends on whether or not the objects which are referred to exist, the principle of contradiction is a necessary but not a sufficient condition of factual knowledge. What is true of possible objects must be true of all actual ones—what is true in all possible worlds must be true of the actual one. But since the converse statement is false, the principles of formal logic cannot be an “organon” of any particular science, that is, a means for attaining knowledge of its subject matter. (See *Kritik der reinen Vernunft*, 2nd ed., introduction to Part II of “Transcendentale Elementarlehre.”)

**CONTEMPORARY LOGIC.** In contemporary logical theory the conception of “true in every possible world” or “true of any objects whatever” has been sharpened into the conception of valid statement forms and valid statements which are well formed in accordance with the precisely formulated syntactical rules of elementary logic—propositional calculus, quantification theory, and theory of identity. A distinction is made between the logical particles, or constants, on the one hand and nonlogical constants and variables on the other. The logical constants are (1) “ $\neg$ ,” “ $\vee$ ,” “ $\wedge$ ,” and other connectives, whose intended interpretations are, respectively, “not,” “or,” “and,” and so on, conceived as connecting true or false propositions so as to form other true or false propositions in such a way that the truth or falsehood of any compound statement depends only on the truth or falsehood of the component statements; (2) the quantifiers “ $\forall$ ” and “ $\exists$ ,” the intended interpretation of which is such that “ $\forall x Px$ ” and “ $\exists x Px$ ” mean, respectively, that for a well-demarked domain of individuals, which may be finite or infinite, every element  $x$  has the predicate  $P$ , and that there exists an individual  $x$  which possesses  $P$  (in addition to such monadic predicates as  $Px$ , such dyadic predicates as  $Pxy$  and polyadic predicates are also admitted, so that, for example,  $\forall x \exists y Pxy$ ,  $\forall x \forall y Pxy$ , and so

on, are also admitted); and (3) the sign “ $=$ ” with the intended interpretation as identity of individuals.

The nonlogical constants are (a) names of specific individuals, such as “Socrates” or, indeterminately, “ $x_0$ ,” (b) names of specific predicates, such as “green” or, indeterminately, “ $P_0$ ” where two predicate names which are truly asserted of the same individuals of the given domain are regarded as naming the same predicate, (c) names of specific statements, such as “Socrates is mortal” or, indeterminately, “ $p_0$ .” The variables are individual variables such as “ $x$ ,” predicate variables such as “ $P$ ,” and statement variables such as “ $p$ .” Variables are either free (or, more precisely, free for substitution by names of corresponding constants) or bound by a quantifier so that, for example, “ $Px$ ” contains a free individual variable and a free predicate variables, whereas  $\forall x Px$  contains only a free predicate variable.

A well-formed formula of elementary logic that contains free variables is a statement form. A statement form is valid if—with the intended interpretation of the logical constants—every substitution instance of it is valid in every nonempty domain, provided that every individual, predicate, and statement variable is replaced by the same individual, predicate, and statement constant wherever it occurs in the statement form. Clearly the laws of thought are valid statement forms in, for example, the following formulations: Principle of identity:  $x = x$ . Principle of contradiction:  $\neg(p \wedge \neg p)$ ,  $\forall x \neg (Px \wedge \neg Px)$ . Principle of excluded middle:  $p \vee \neg p$ ,  $(\forall x Px) \vee (\exists x \neg Px)$ . It is equally clear that many other well-formed formulas such as  $\neg\neg p \vee \neg p$  are valid. Valid statement forms that contain only statement variables have been called tautologies by Wittgenstein.

The great precision and clarity given to the conception of the laws of thought as principles of formal logic has, however, not lifted them out of the range of philosophical controversy. Thus, intuitionist philosophers of mathematics argue that the principle of excluded middle is valid only for finite domains and that the extension of its validity to the nonfinite domain of arithmetic is based on the mistaken notion of an actually infinite domain of natural numbers, a notion that unjustifiably assimilates the number sequence to a finite class of objects. Similarly, they deny the validity of other classically valid statement forms, such as  $\neg\neg p \rightarrow \neg\neg p$ .

The results of modern mathematical logic have deprived the laws of thought of their privileged status as the supreme principles of all logical truths. But since these results do not imply that there is only one true logic, the choice between classical elementary logic, intuitionist

logic, and perhaps some other logical theories still depends, at least at the present time, on extralogical, philosophical arguments.

## LEBENPHILOSOPHIE

See *Philosophical Anthropology*

## LE CLERC, JEAN

(1657–1736)

Although Jean Le Clerc, the philosopher and Arminian theologian, was not a major figure, he had a considerable influence on eighteenth-century French philosophy. He championed rational religion, which was later widely accepted, and was also the first disciple of John Locke, whose work he introduced to Continental audiences. Through his learned reviews, the *Bibliothèque universelle et historique* (1686–1693), the *Bibliothèque choisie* (1703–1713), and the *Bibliothèque ancienne et moderne* (1714–1727), he stated and defended Locke's views.

Raised in Geneva during a period of strife over the Calvinist dogma of predestination, Le Clerc was a confirmed rationalist when he left the Geneva Academy. He believed that the fundamentals of Christianity (God's existence and the divinity of Scripture) are capable of demonstration. Scripture must be rationally interpreted; one cannot believe what conflicts with rational truths, and doctrines over which rational men disagree are not essentials of faith. For this doctrine, Le Clerc was expelled from Geneva in 1683.

He went first to England and then settled permanently in Holland, a haven for political and religious exiles. He found a spiritual home in the rationalistic Remonstrant Church and soon became professor of Hebrew, philosophy, and belles-lettres at the Remon-

strant College at Amsterdam. At this time Le Clerc met John Locke, then in exile, and acquired a systematic philosophy. In 1688, two years before the English publication of the *Essay concerning Human Understanding*, he printed a long French summary in his *Bibliothèque universelle*. He also helped popularize many other English writers and published a long review of George Berkeley's *New Theory of Vision* in the *Bibliothèque choisie* (1711).

Le Clerc's philosophy was purely Lockean. He rejected innate ideas, used the notion of abstract ideas, and continued the critique of the idea of substance. He opposed René Descartes, Nicolas Malebranche, Benedict de Spinoza, and Gottfried Wilhelm Leibniz because their theories claim knowledge beyond human ideas. However, whereas Locke was indifferent to the rise of radical skepticism, Le Clerc was quite critical of it. He vigorously asserted the reality of human knowledge, although restricting its scope, and tried to refute each of the leading skeptics (Sextus Empiricus, Michel Eyquem de Montaigne, Pierre-Daniel Huet, and Pierre Bayle). He became involved in an acrimonious dispute with Bayle, who argued that the conflict between fundamental Christian doctrines and the principles of reason must be considered as a basis for skepticism regarding reason. To Le Clerc, Bayle's view led to irreligion or fanaticism. He insisted that reason is the criterion of truth and that faith and reason are compatible.

## LE CLERC, JEAN [ADDENDUM]

Although embroiled in many intellectual controversies throughout his career, Jean Le Clerc's repeated disputes with Pierre Bayle were of greatest significance. Bayle had argued that Christianity strengthens Pyrrhonian skepticism in that a number of axioms of logic and metaphysics are contradicted by Christian dogmas. Therefore, even self-evidence (*évidence*) is not an infallible criterion of truth, since these axioms are self-evident, yet false. In the same vein, Bayle argued that one cannot conceive how an omnipotent and omnibenevolent God could allow human suffering either here or in the afterlife. Le Clerc replied that God's justice demands that those who freely choose to sin be punished, but conceded that the torments of hell might not be eternal.

Similarly, when Le Clerc championed the notion of plastic natures—insentient, immaterial substances causally responsible for the organization of animal bodies—Bayle argued that the hypothesis undermined the most compelling argument for God's existence by severing the conceptual connection between complex effects and conscious design.

Underlying their debates were two fundamentally different conceptions of the relation between faith and reason. For Le Clerc, Bayle's insistence on the irrationality of Christianity constituted a thinly veiled attack on religion itself, whereas Bayle saw Le Clerc's demand that scripture be interpreted according to rational principles as ultimately leading to deism or atheism.

## LEGAL POSITIVISM

In many discussions of the nature of law the terms “legal positivism” and “natural law” are assumed to be the names of rival theories. In fact, each of these designations stands for a number of different and logically distinct doctrines, with the unfortunate result that in many disputes between “positivism” and “natural law” the precise point of conflict is unclear and the classification of a legal theorist as a “positivist” may afford very little indication of the nature of his theory. Thus, what is called the imperative theory of law, that is, the view that laws are commands, is usually treated as a central tenet of legal positivism; but although Jeremy Bentham and John Austin held this view, Hans Kelsen (usually regarded as the most uncompromising of modern legal positivists) held neither this view nor its corollary, that international law is not really law but a mere species of morality. Similarly, “legal positivism” is sometimes used as a designation for a thesis concerning the nature of moral judgments, including those made about the justice or injustice or the goodness or badness of human laws. This is the thesis (sometimes termed “noncognitivism”) that such judgments cannot be established by reasoning but are merely expressions of human feelings or choices or “prescriptions.” Kelsen held this view of moral judgments but Bentham and Austin did not. Bentham and Austin were both utilitarians who considered that moral judgments could be rationally established by the application of the test of utility, which according to Austin was also an “index” of God’s commands.

A variety of other doctrines about law, besides those mentioned above, have been described as “positivist.” These include the doctrine that although law and morals may often overlap or be causally related, there is no necessary or conceptual connection between them; the doctrine that judicial decisions are or should be deducible by logical means from legal rules and involve no choice or creative activity on the part of the judge; and the doctrine that there is an absolute moral obligation to obey the law, however morally iniquitous it may be.

The etymology of the word *positivism* and cognate expressions offers little guidance to its use in the philosophy of law. Since at least the fourteenth century, the expression “positive law” has been used to refer to laws

laid down or made by human beings in contrast to natural or divine law, which is regarded as something discovered and not made by man. But the expression “positive law” has also long been used to refer to any law brought into being by a command or act of will and so includes the law of God as well as human legislation. More recently, the use of the expression “legal positivism” has been colored by the philosophical sense of “positivism” introduced by Auguste Comte. In this sense a “positivist” doctrine is one according to which nothing can be truthfully (or in later versions, meaningfully) said to exist unless it is in principle observable by human beings.

More important for legal theory than the etymology of the word is the identification and classification of the principal issues in relation to which philosophers of law or legal theorists have advanced views commonly styled positivist. Five such issues may be distinguished, and the discussion of these constitutes the remainder of this entry.

### POSITIVISM AS A THEORY OF A FORM OF LEGAL STUDY

Bentham, Austin, and Kelsen, while differing as noted above on certain points, agreed that there is an important branch of legal study distinguished by two features: that it is not concerned with any ideal law or legal system but only with actual or existent law and legal systems; and that its concern with law is morally, politically, and evaluatively neutral. The object of this form of legal study is the clarification of the meaning of law, the identification of the characteristic structure of a legal system, and the analysis of pervasive and fundamental legal notions, such as right, duty, ownership, or legal personality. Bentham, Austin, and Kelsen were all concerned to distinguish such an “analytical” jurisprudence, as this form of legal study is now called, from critical or evaluative studies of the law, and they have stressed the importance of this distinction. However, none of these theorists—though the contrary is sometimes suggested—considered that analytical jurisprudence excluded critical or evaluative studies of the law or rendered them unimportant.

It should be observed that belief in the importance of analytical studies of the law does not strictly entail belief in other forms of legal positivism, though in fact it has usually been associated with one or more of these other forms. It is also true that not all morally or evaluatively neutral studies of the law need take an analytical form. Many sociological descriptions of the operation of law and society, and many sociological theories of the causal connection between law and other social phenomena are

also evaluatively neutral, at least in intention. Hence, some of these, too, have at times been regarded as forms of positivism.

### POSITIVISM IN THE DEFINITION OF LAW

The definition of law as the command of the “sovereign” is no doubt the most prominent example of a form of positivism. But the expression “positivist” is also used in a wider sense to include any doctrine according to which law is defined as the expression of human will or as man-made, even if it does not take the form of a command. Thus, both the doctrines known in American jurisprudence by the loose title of “legal realism,” according to which only decisions of courts and the predictions of such decisions are law, and those theories of international law which insist that it is composed exclusively of rules originating in custom or in agreements between states are usually described as positivist. It is to be noted, however, that both Bentham and Austin, who defined law as the command of a sovereign, extended the notion of a command to include both customary law and judge-made law. For this purpose they invoked the idea of a “tacit,” or “indirect,” command resting on the principle that whatever the sovereign permits he commands.

### POSITIVISM AS A THEORY OF THE JUDICIAL PROCESS

Sometimes the term “legal positivism” is used to refer to the view that correct legal decisions are uniquely determined by preexisting legal rules and that the courts either do or should reach their decisions solely by logical deduction from a conjunction of a statement of the relevant legal rules and a statement of the facts of the case. This is sometimes referred to as the “automatic” or “slot-machine” conception of the judicial process; but it is doubtful whether any Anglo American writer who is usually classified as a positivist would subscribe to any such view. It is true, however, that Bentham and Austin thought that the area of choice allowed to judges by a system of case law was excessive and led to great uncertainty, and they claimed that this could and should be drastically reduced by classification and codification of the law in clear and detailed terms. But they were both well aware of the fact of judicial legislation and creative activity, and as noted above, they sought to reconcile this fact with their definition of law as the command of the sovereign by using the idea of a tacit command. The doctrine that a judge should not exercise choice in his decision of cases but should merely be the mouthpiece of previously exist-

ing law is to be found in the works of eighteenth-century writers not usually classed as positivists, such as Baron de Montesquieu’s *L’esprit des lois*. They looked upon this doctrine as a corollary of the doctrine of the separation of powers and as a protection of the individual against arbitrary decisions, uncertainty, and privilege.

### POSITIVISM AS A THEORY OF LAWS AND MORALS

It seems that all writers classed as positivists have subscribed to the view that unless the law itself provides to the contrary, the fact that a legal rule is morally iniquitous or unjust does not entail that it is invalid or not law. This view may also be expressed as the claim that no reference to justice or other moral values enters into the definition of law. “The existence of law is one thing; its merit or demerit another” (Austin). “Legal norms may have any kind of content” (Kelsen). Such a denial of a necessary or definitional connection between law or legal validity and morality is perhaps the principal point of conflict between legal positivism and theories of natural law. For nearly all variants of the latter refuse to recognize as law or legally valid rules that violate certain fundamental moral principles. It is, however, important to remember that this denial of a necessary connection between law and morals is compatible with the recognition of many other important connections between them. Thus few, if any, positivists have denied that the development of the law has in fact been influenced by morality or that moral considerations should be taken into account by legislators and also by judges in choosing between competing interpretations or conflicting claims as to what the law is.

### POSITIVISM AND THE OBLIGATION TO OBEY LAW

If positivism has become a pejorative term, it is very largely because it has been identified by some critics with the claim that where a legal system is in operation, there is an unconditional moral obligation to obey the law, however unjust or iniquitous it may be. This claim may be based either on the view that there is a moral obligation to obey law as such or on the belief that the actual existence of a legal system, however oppressive or unjust, provides large numbers of human beings with a minimum of peace, order, and security and that these are values that no individual is morally justified in jeopardizing by resistance to the law. The German legal theorist K. M. Bergbohm, perhaps the best-known legal positivist in continental Europe in the nineteenth century, held this view; but though he in fact also subscribed to other forms

of legal positivism described above, this view is logically quite independent of them. Utilitarian positivists, such as Bentham and Austin, held that resistance to law might be justified in extreme cases, but before this step was taken, careful calculations in terms of utility were necessary to ascertain that a balance of good over evil was likely to result. They criticized the doctrine of natural law and natural rights not because they believed that there was an unconditional obligation to obey the law, but because in their view these doctrines presented standing temptations for men to revolt without making such calculations of the consequences.

H. L. A. Hart (1967)

## LEGAL POSITIVISM: ANGLO-AMERICAN LEGAL POSITIVISM SINCE H. L. A. HART

### HART'S POSITIVISM AND DWORKIN'S INITIAL OBJECTIONS

Herbert Lionel Adolphus Hart's version of legal positivism, developed in *The Concept of Law* and refined in the Postscript to the second edition, has been the centerpiece in the development of contemporary legal positivism as well as the focal point of the strongest and most interesting objections to it in the philosophy of law. Hart's own argument builds on the work of positivists who preceded him. In particular, Hart seeks to address and correct the main shortcomings he identifies in the theories of law offered by John Austin and Hans Kelsen. Both Austin and Kelsen thought that laws are a distinguishable subset of norms, identifiable by their possession of an intrinsic and necessary property. In other words, they saw the fundamental project of jurisprudence as determining what it is to be *a law*. For Austin, laws are orders or commands backed by a threat of sanction issued by a sovereign. The threat of sanction distinguishes a command from a plea or a request while the fact of issuance by a sovereign distinguishes legal commands from all other commands. A sovereign, properly so called, is a person who has secured the habit of obedience from the vast majority of the populace and who is not in the habit of obeying anyone. Like Austin, Kelsen holds that sanctions are both intrinsic to law and necessary for their existence. Unlike Austin, however, he argues that although sanctions are imposed on citizens, legal norms are directives to officials to impose sanctions against citizens in the event that they behave in ways identified as sanctionable by the law.

One of Hart's most important claims is that laws are irreducibly of at least two sorts: (1) power-conferring, or secondary, rules; and (2) primary rules that impose obligations to act or to forbear from acting. Power-conferring rules are not themselves reducible to rules that impose obligations because the failure to comply with a power-conferring rule renders one's action a nullity in law and is

neither the basis of liability nor a liability itself. An act nullified is one that does not have the legal effect a successful exercise of the legal power would have produced. A failure to exercise a power according to the required formula is not a failure to comply with an obligation to act or to forbear from doing so. Nullification, in turn, is no sanction. In one fell swoop, then, Hart undermines both the claim that legal rules are of one type and that what is distinctive of the type is the presence of sanctions.

Power-conferring, or secondary, rules are themselves of two kinds: private and public. Private secondary rules empower those governed by law to alter the normative relations among themselves (e.g., as in transferring private property through contracts, marital agreements, and wills) and a legal power to call upon the state's resources to enforce those relations. Public power-conferring rules create and regulate the offices to which legal authority attaches, and their existence is implicated in the very idea of private power-conferring rules as well. For Hart, the most important secondary rule is what he terms the rule of recognition. This rule sets forth the conditions that must be satisfied in order for a norm to constitute part of the community's law and in so doing constitutes an identity condition of a legal system. Beyond that, the rule of recognition both confers a power and imposes a duty on certain officials to evaluate conduct in the light of the norms that satisfy the criteria of law it sets forth.

It is important to Hart's account that rules are expressed in general terms. Such terms possess a core of settled meaning and a penumbra of disputed meaning. This maps on to the distinction between those cases in which no competent speaker of a language can legitimately deny that a rule applies (the core of a rule) and those cases in which reasonable, competent speakers of a language can legitimately disagree (the penumbra). In cases falling within the core of a rule, the law settles the matter and a judge is under a duty to apply the law to the facts at hand. In cases falling within the penumbra of a rule, there is no settled law on the matter and a judge must exercise discretion. The scope of judicial duty is fixed by settled meaning or practice. Where either meaning or practice runs out, judicial discretion—a rationally constrained power, not a license—enters. Some contend that Hart believed that the function of law is to guide conduct by reasons, but this is not his view. Whereas the heart's natural function is to pump blood, the law has no such function. Instead, it can serve any number of human ends and purposes—some laudatory and others evil. Hart's view is that whatever business law does, it goes

about it by regulating conduct through rules that are reasons. That is its mode of operation, not its function.

For Hart, law is to be understood in terms of its structure—in the union of primary and secondary rules—not in terms of its having a natural function. Thus, Hart's positivism can be identified with the following tenets: laws are rules; legal rules are of two irreducible types—power conferring and duty imposing. Wherever there is law, there is a rule of recognition that sets out the criteria for the laws of a community. That rule is part of the identity conditions of a legal system. All rules are expressed in general terms, and the set of norms that satisfy the criteria of legality are finite. Thus, there will be gaps in meaning and in settled or controlling law. Discretion is inevitable.

Beyond his particular disagreements with them, Hart's positivism shares with its predecessors a view about the relationship between law and morality. This is the view that there is no necessary connection between law and morality—the so-called separability thesis. Most commentators take the separability thesis to be the *sine qua non* of legal positivism, but some recent work on legal positivism has raised doubts about the centrality of this claim to the field. Still, there is no denying that Hart was committed to it.

For our purposes, the important features of Hart's positivism are its commitment to judicial discretion and the rule of recognition. The set of binding legal standards in any community is determined by the criteria of legality in that community. Those criteria are set forth in a rule of recognition whose existence and content is fixed by the critical, reflective attitude (the internal point of view) of officials—in particular, judges. The set of standards or rules that satisfy these criteria is finite and thus, in principle, there will be disputes that are not resolved by available legal resources. Judges will be required, therefore, to exercise discretion: a legal power to rely on non-legal standards, some of which will be moral standards, to resolve legal disputes. This is the so-called discretion thesis.

## DWORKIN'S FIRST OBJECTIONS

Discretion is inevitable where settled law runs out. It is this feature of Hart's account that Ronald Dworkin exploits and which forms the basis of his first and most famous objections to Hart's account. Cases in which the *law runs out* are *hard cases*. Because discretion is a constrained power, judges must decide hard cases by appealing to rationally defensible standards. *Ex hypothesi*, such standards are not part of the law, but they must be prin-

ciples or other standards that constitute good reasons or justifications for the decisions a judge reaches at law. Dworkin notes that judges do not act as if the standards to which they appeal in deciding hard cases are optional for them. If we allow, instead, that the moral principles to which judges appeal in deciding hard cases are sometimes legal, binding because they are law, and law because they express an appropriate dimension of morality, one must abandon not only the discretion thesis but the other basic tenets of positivism as well—such is the nature of the relations among them.

First, if the moral *principles* to which judges appeal in hard cases are even sometimes law, then it cannot be true that all laws are *rules*. Second, if these principles are law, then they are not law in virtue of their satisfying the rule of recognition. They have no institutional source in that sense. This suggests that their legality depends on their content, in particular, on their moral value or worth. But if they are binding in virtue of the fact that they express an appropriate aspect of fairness or justice, then the separability thesis—which appears to reject the claim that legality can depend on morality—must be abandoned. So, too, must the rule of recognition, for it is not true that wherever there is law, there is a Master Rule that determines fully a community's binding legal standards.

## EXCLUSIVE AND INCLUSIVE LEGAL POSITIVISM

Positivists have adopted one of two approaches to Dworkin's objections. Common to both is a willingness to grant one of Dworkin's main premises, namely, that at least in some cases the moral standards judges apply are binding on them, not optional. These approaches differ with respect to the second premise: In virtue of their being binding on officials, are those standards part of the community's law?

Those who reject the second premise are exclusive legal positivists (exclusivists); those willing to accept both premises are inclusive legal positivists (inclusivists, incorporationists, or soft positivists). Though he does not employ these labels, Joseph Raz (1939–) is most often cited as the leading positivist of the first sort whereas Jules Coleman (1947–) is usually cited as the most prominent advocate of the latter approach. Both approaches reject Dworkin's claim that the binding nature of moral principles undermines positivism, but for importantly different reasons.

Raz emphasizes a significant distinction between a norm being binding on an official (e.g., a judge) and its being binding in virtue of its being the law of his com-

munity. Laws of jurisdiction *A* may, under certain conditions, make laws of jurisdiction *B* binding on officials in jurisdiction *A*. That is not enough to make the laws of jurisdiction *B* laws of jurisdiction *A*. Understood in this way, Raz's argument is that Dworkin has not made the case that moral principles are part of the law. In fact, however, Raz advances the much stronger claim that if moral principles are binding on officials, they can only bind in the way that norms of other jurisdictions do. This stronger argument relies only on general considerations regarding the relationship between the concepts of law and authority and from no distinctive commitments of legal positivism. Instead, Raz begins with a putative conceptual truth about law: that it necessarily claims to be a legitimate authority. As long as governance by law is not an incoherent idea, then law must be the sort of thing of which the claim to authority could be true—even if, as a factual matter, it always turns out to be false. This feature of the claim to authority constrains the kind of thing law can be, but the exact constraints it imposes depends on what the claim to being a legitimate authority entails.

On Raz's account, an authority mediates between persons and reasons in such a way that in accepting an authority, an agent is (with rare exceptions) precluded from appealing directly to the reasons that would justify the authority's directives. If one appeals to what Raz calls the *dependent reasons* in order to identify what the law is or to determine its content, then one vitiates the law's claim to authority. Since the dependent reasons on which law relies and which justify laws are moral reasons, it follows that morality itself cannot be a condition or ground of law. Instead, all law must have what Raz calls a social source. Thus, the claim to authority in conjunction with Raz's theory of authority entails what has come to be called the sources thesis. Some positivists, most notably John Gardner (1965–), advance the view that the core of legal positivism is the sources thesis but note that the thesis itself derives from no claim of legal positivism at all. It derives, instead, from the conjunction of a conceptual claim about law and a theoretical and quite general, if controversial, theory of the meaning of authority.

The inclusivist grants both of Dworkin's premises: that moral standards can sometimes be legally binding and that they can sometimes be part of the community's law. His strategy is to show that none of Dworkin's objections to legal positivism are entailed by accepting these two premises.

Coleman argues that it cannot be Dworkin's view that all moral principles are law merely in virtue of their content or moral merits. That would make all of morality

part of the law everywhere and always. Put another way, there must be some institutional or social fact that makes some moral principles part of the law in the jurisdictions in which they are law. But then it would have to be that fact that makes them law, not their individual merits. Coleman then argues that there is no reason in principle why the relevant social or institutional fact that renders moral principles law could not be agreement among officials to count those moral principles as law. Nothing in legal positivism, in any case, precludes that.

### THE NEXT PHASE

It is important to draw a distinction that is rarely explicitly made but which is central to understanding the various current disputes among positivists and between positivists and their critics. This is the distinction between the grounds, or sources of law, on the one hand, and the grounds of the grounds of law, on the other. The grounds, sources, or criteria of law refer to the *test* for legality within a community. Both the sources thesis and inclusivism are claims about possible constraints on the grounds of law. The sources thesis claims that all such grounds must be social sources; the inclusivist denies that. Dworkin's argument in "The Model of Rules" is that morality can be a ground of law, which is incompatible with the sources thesis and thus with exclusive legal positivism but not with inclusivism.

The fact that inclusivism shares with Dworkin the view that morality can be a source of law has led Dworkin to chide inclusivists, especially Coleman, for having an underdeveloped version of his view. The criticism cuts no ice, however. The core of legal positivism is not a claim about the grounds of law; it is a claim about the grounds of the grounds of law. And on this score, both exclusivists and inclusivists agree that only social facts—facts about individual behavior and attitude—can be the grounds of the grounds of law. What distinguishes positivists from one another is what they take this claim about the grounds of the grounds of law to allow. Inclusivists believe that commitment to social facts at this level does not impose any constraints on potential grounds of law. They hold, moreover, that nothing about the nature of law or authority does either. In contrast, exclusivists hold that facts about the nature of law, in particular its role in our practical lives, imposes constraints on potential grounds of law. Thus, exclusivists accept the sources thesis whereas inclusivists do not. That does not render the inclusivist a proto-Dworkinian.

The sources thesis is said to follow from the conjunction of the claim that law necessarily claims author-

ity in conjunction with a particular account of what that claim requires. In order to escape this implication, the inclusivist might reject the conceptual and/or the theoretical claim, reject the alleged relationship between them, or accept both but deny that they entail the sources thesis. Coleman, for one, rejects both of the premises of the argument, but he is willing to accept them because, he argues, they do not in fact entail the sources thesis.

Roughly, his argument is this: Whereas appealing to the dependent reasons that purport to justify an authoritative directive in order to determine the directive or its content undermines the directive's claim to authority, it does not follow that every moral principle offered as a condition of legality for norms must be among the dependent reasons that justify the particular directive in question. For instance, a clause making *equal protection of the law* a condition of legality for every putative legal rule need not be a reason that justifies any particular law—one outlawing murder, for example. There is nothing in the logic of law that precludes reasons *R1* through *R5* being the grounds that justify a law *L*, but reasons *R6* through *R9* being the conditions of the legality of *L*. The mere fact of appealing to moral premises as the conditions of law does not mean that one is appealing to the reasons that would be offered to justify the law.

As Raz characterizes it, the theory of authority claims that one cannot appeal to moral principles to identify the law or to determine its content. This is an epistemic constraint on identifying law and determining its content. But inclusivism is a theory about the grounds of law: the conditions that make law *determinate*—what makes it the law. Inclusivism is, in a broad sense, an ontological or metaphysical theory that may well be untouched by the epistemic constraints that are said to fall out of the appropriate theory of authority.

### DWORKIN AND THE POSITIVISTS REDUX

Dworkin has not been persuaded by either the inclusivist or the exclusivist strategies, but he has focused primarily on the inclusivist strategy. Recall that Coleman responds to Dworkin's objections to Hart by noting that moral facts cannot be law merely in virtue of their being moral facts, for that would render all moral facts legal facts. Instead, the positivist need not deny that moral facts can be legal facts; he need only argue that moral facts are legal facts in virtue of certain legally significant social facts about them—typically acceptance among officials of their status as part of the law. Any such account of the

way in which social facts make moral facts part of the law is going to be a form of legal positivism.

Dworkin has responded in two ways: one positive, the other critical. On the one hand, he has developed an argument, expounded primarily in *Law's Empire*, designed to show how certain kinds of moral facts, not just social facts, turn other moral facts into law. This is his *theory of constructive interpretation*. On the other hand, he has offered a variety of interesting and important objections to the inclusivist claim that moral facts can be grounds of law and, ultimately, to the claim that they can be grounds of law in virtue of certain social facts or practices.

The point of departure for some of these objections is the idea that morality is inherently controversial, and this fact about it is incompatible with the claim that it can be a condition of legality. At one point, Dworkin argued that positivism holds that the function of law is to guide conduct, in part by resolving disputes and disagreements about what one ought to do. This is one reason for his oft-repeated view that legal positivists identify law with plain or hard fact—the sort of thing one could determine with near certitude by looking it up in a book. Morality is too controversial for its inclusion in law to serve this function. This objection has no force. Presumably, one role of morality in our lives is to guide conduct. If morality is capable of guiding conduct, therefore, it is capable of guiding conduct whether it is part of the law or not. Beyond that, nothing in legal positivism would suggest that legal disputes must be resolved in a way that is essentially uncontroversial.

A more serious version of the objection maintains that the essentially controversial nature of morality means that judges applying the criteria of legality that includes morality will often disagree, and this level of disagreement is incompatible with the positivist claim that at the foundation of law resides a social rule, namely, the rule of recognition. A social rule has two dimensions: shared, convergent behavior and a shared critical, reflective attitude toward that behavior. One consequence of allowing that morality might be a condition of legality is widespread disagreement among officials that is incompatible with the requisite agreement necessary for the criteria of law to be determined by a social rule among officials.

Note that the key here is the connection between the grounds of law and the grounds of the grounds of law. If morality can be a condition of legality (a ground of law), as inclusivists claim, then the foundation of law (the grounds of the grounds of law)—the rule of recogni-

tion—cannot be a social rule. The claim that the grounds of the grounds of law are social facts precludes moral facts from being among the grounds of law. Positivism cannot have it both ways. The problem with this objection is that it treats disagreement about whether the grounds of law are satisfied as if it entailed disagreement about what the grounds of law are. You and I can disagree about whether someone is intelligent while agreeing that we should only hire intelligent people for our company. Disagreement about whether the conditions of legality are satisfied is perfectly compatible with agreement about what those conditions are. If any sort of agreement is required in order for there to be a rule of recognition, it is agreement of the second sort.

At one point, Dworkin responded that all disagreements about whether a rule applies could be formulated as disagreements about what the rule is, thereby raising doubts about whether the distinction Coleman points to between agreement about the criteria and agreement about its applications is helpful. Dworkin's response has proven unpersuasive because it identifies a rule with the set of its instances, which cannot be a plausible understanding of what it is to be a rule. Dworkin eventually adopted a more interesting line of attack, which begins by reflecting on a more general philosophical concern regarding the sort of agreement that is necessary in order for disagreements to make sense; that is, for individuals actually to be disagreeing with one another rather than merely talking past one another. He associates legal positivism with the view that judges and other officials must agree on the grounds of law in order for their disagreements about what satisfies those grounds to be meaningful.

If he has diagnosed the commitments of legal positivism correctly, Dworkin may have identified a powerful objection to it since it appears as if legal positivism cannot explain the possibility of disagreement about what the grounds of law are. Yet such disagreement is a significant feature of legal practice. At bottom, Dworkin has a picture of legal positivism that is very likely warranted by Hart's formulations and much of the positivist literature that has followed. In this picture, legal positivism represents a certain architectural rendering of law and of legal practice. Law is a closed normative system whose boundaries are determined by the scope of agreement. It has a set of initial premises (we can think of these as rules of recognition) whose existence depends on agreement about what they assert or prescribe. Once these rules are in place, we can have a practice called law. These rules make the practice possible and are both inside and out-

side the practice. They are part of the law, but not, as it were, in the mix. If anything, they are like Carnapian *meaning postulates*. They are not subject to revision from within the practice; they are immune in that sense. If the practice fails to achieve the aims we have for it, we can change the ground rules and have a new practice. But we do not have a practice that changes from within. We can disagree about what falls within the practice, but we cannot disagree about what the rules are that constitute the practice itself.

Dworkin's most interesting objections to legal positivism can be recast as trying to shed doubt on this *architecture* of the law. For Dworkin, the fluidity of the boundaries between law and other normative systems, between what is inside and outside law, his deep anti-Archimedianism, are all different ways of getting at the same problem. Dworkin is Willard Van Orman Quine to legal positivism's Rudolph Carnap.

As Coleman and others have argued, the heart of legal positivism is the claim that the grounds of the grounds of law are social facts—facts about behavior and attitudes. It is not obvious that this claim entails either of Dworkin's objections to positivism, namely, the claim that positivism cannot account for disagreement about the grounds of law or the related claim that positivism imposes a Carnapian architecture on legal practice. In fact, the Quinean picture of legal practice is completely compatible with positivism.

## ANOTHER PICTURE

If, for the sake of simplicity, we use the term *rule of recognition* to refer to the grounds of law, then positivism can hold that the rule of recognition is at the *center* of law, not at the foundation of law. Thus, the rule of recognition is in the mix, subject to revision and even abandonment on the same grounds as are other rules and standards within law. There is a distinction worth emphasizing between the *existence* conditions of a rule and its *revisability* conditions. The rule of recognition's special status, moreover, is not a function of it being at the foundation of law but of its inferential importance. Much of the rest of the law of particular communities makes sense inferentially in virtue of the rule of recognition. As the importance of various grounds of law to inferences that warrant other settled areas of the law diminishes, the likelihood of revising that *ground of law* increases.

Nor is there a distinctive problem in understanding disagreement among participants about the grounds of law, for the rule of recognition is not rigidly fixed by agreement. The complexity of any particular legal prac-

tice is likely to mean that there will be different and quite varied views about which putative grounds of law are more or less central to the practice in place.

More importantly, the claim that the content of the rule of recognition is fixed by social facts does not entail that the content of the rule, or its proper formulation, is transparent or otherwise available to officials—that is, those whose conduct is regulated by it. No more so must the content of the rule be transparent than must the rule governing the use of personal pronouns be accessible to ordinary speakers of a language whose speech it governs. If transparency of the rule to officials is required to coordinate their behavior—and it is an empirical question whether in fact it is—sharing the rule in the sense Dworkin attributes to positivism is no more than an efficiency condition of law and not a theoretical commitment of legal positivism. There is nothing in the idea that law rests ultimately on social facts that is itself incompatible with disagreement about the grounds of law. Still less does the claim that law is created by social facts alone entail the architectural view of law that renders the grounds of law immune to revision from within.

Positivism need not necessarily be understood in the way sketched here. Rather, the above sketch is designed to suggest only that the social facts thesis does not render positivism vulnerable to the charge that it cannot explain disagreement about the grounds of law. Nor does the social facts thesis leave positivism vulnerable to the charge that it pictures law as *shut off* from or *bounded* by other normative systems (other legal systems and other schemes of regulating conduct) in the way the architectural picture of a definite inside and outside of law suggests. Whether this line of argument on behalf of positivism proves ultimately persuasive remains very much an open question.

Jules L. Coleman (2005)

## LEGAL REALISM

Beginning about 1920, an iconoclastic group of American legal writers, led by K. N. Llewellyn, Walter Wheeler Cook, Jerome Frank, Herman Oliphant, and Underhill Moore, denounced the established legal tradition as formalistic and conservative. That tradition, they charged, wrongly saw the law as a complete and autonomous system of logically consistent principles, concepts, and rules. To apply the law was to unfold the ineluctable implications of those rules. The judge's techniques were socially neutral, his or her private views irrelevant; judging was more like finding than making, a matter of necessity rather than choice. The realists, by contrast, saw legal certainty as rarely attainable and perhaps even undesirable in a changing society. In their view the paramount concern of the law was not logical consistency but socially desirable consequences. Law was an instrument of government, and jurisprudence should focus less on legal concepts than on social facts.

## BASIS OF LEGAL REALISM

According to the realists, legal decisions were not compelled; choice was necessary at every step. Just as lawmakers built their ideological preferences into a statute, judges built theirs into their formulation of “the facts” of a case. Legal concepts represented nothing more than tentative decisions to consider diverse cases identical with respect to a given concern. Unless readjusted continually, such concepts could be rendered irrelevant by changing circumstances and purposes.

Realism meant opposition to illusion or pretense, sometimes to abstractions or appearances. Judges had always made law, but now, the realists insisted, they must know and say that they did. They must acknowledge their responsibility instead of attributing their choices, through tortured technicalities, to the compulsions of legal doctrine. (Oliver Wendell Holmes, the favorite judge of the realists, had said that law becomes more civilized as it becomes more self-conscious.) If the judges’ latent motives and official reasons were reconciled, their judgments would be not only more honest but more informed. Moreover, assumptions about the nature of law could then be considered in the light of scientific knowledge of the actual workings of legal institutions, and assumptions about social policy could be seen in the light of scientific knowledge about society. The realists took the possibility of such scientific knowledge for granted. They further assumed that society had its own mechanisms for effecting changes and that, in general, the law should reflect social change, not shape it. Yet the realists avoided the conservative conclusions that usually accompany this view, for being, above all, reformers, they believed that the constant flux of modern society required a legal system flexible enough to match its pace.

Like other iconoclasts, the realists saw rationalization and self-deception beneath traditional claims to objectivity. They “saw through” appearances, theories, and justifications to underlying motivations or functions. They sought complete candor. The natural sciences provided their model; John Dewey, their philosophical vocabulary. They also drew on the tradition of sociological jurisprudence, which in both Europe and America had already prescribed the study of society as the proper way to discover social preferences beneath the neutral forms of the law.

These ideas were more influential in America because of the unique power of American judges to declare statutes unconstitutional. Moreover, the differences among the states in their approach to identical legal problems frustrated belief in inexorable solutions. Thus,

Holmes had asserted since the 1870s that “the true grounds of decision are considerations of policy and of social advantage.” John Chipman Gray saw the sources of law brought to life only in the crucial act of judicial interpretation; he believed that since courts have the last word, “all law is judge-made law.” At the turn of the twentieth century Roscoe Pound attacked “mechanical jurisprudence,” distinguished “law in action” from “law in books,” and conceived of a sociological jurisprudence that would increase legal sensitivity to social needs and to the social effects of legal rules.

The realists were distinctive, however, in their preoccupation with the processes of judicial decision, with how law is made. They put forward a theory of precedent starting from Llewellyn’s assertion that “a case stands not for one thing, but for a wide variety of things.” Following Dewey, for whom a judgment was always somebody judging something, they stressed the crucial position of the judge who decided whether a case was “the same” as a previous case—that is, which similarities between them should be considered important. Skeptical of principles abstracted from a particular factual context, the realists found support in the common-law tradition that principles should evolve from rather than precede the disposition of particular cases. They trusted the judge’s trained reaction to the entire set of facts before him—his “intuition of experience” (Oliphant), which depended on “knowing how” rather than “knowing that”—much more than they trusted the justification he supplied in his opinion. They therefore wanted precedents to be based on what a court actually did in response to a particular set of facts, not on its language. But emphasizing particularity means getting less direction from previous cases, for facts vary enormously. The more that precedent presupposes factual similarity between cases, the fewer its applications; future judges are freer. No two cases are identical, and if any distinction distinguishes, no precedents are possible. Logically, it is always open to a judge to decide either way, to see a previous case as a precedent or not. Some realists therefore concluded that every decision was a “free” moral decision. This conclusion, shorn of the analysis of the logic of precedent behind it and interpreted simply as giving judges greater discretionary power than the traditional view allowed them, was seen by most of the legal community as the essential message of legal realism.

## RISE OF LEGAL REALISM

Grant Gilmore has related the realist’s view of precedent to the remarkable increase, starting around 1890, in the

amount of litigation and in the proportion of cases reported, an increase that threatened to inundate a system depending on “a comfortable number of precedents, but not too many.” According to Gilmore, the realists responded to this crisis by allowing fewer cases to count as precedents. In this way, Gilmore has noted, legal realism was part of the major social developments of 1880–1930, notably the rise of urbanism and modern industrialism and technology; during this period realism was not confined to the law. The search for fact, for concreteness, for the truth behind appearances, can be found everywhere—in literature, in painting, in social criticism. Consider, for example, the salient characteristics of a movement quite unrelated to legal theory—progressive education. For both progressive education and legal realism, pursuing “reality” meant going from theoretical formulas to what worked in practice, from books to life, from text to context, from passively and mechanically transmitting a received tradition to actively and flexibly responding to each pupil or case. Both progressive education and legal realism flourished in the 1930s during the New Deal. Both can be seen as to some extent a response to sheer numbers, to universal education and the increase in litigation, respectively.

### INFLUENCE OF LEGAL REALISM

Throughout the law the realists contributed to greater candor about the social bases of decision. They also suggested specific improvements in practical areas of the law—for example, Charles E. Clark on covenants’ running with the land, Cook on conflict of laws, Arthur Corbin on contracts, Leon Green on torts, and Llewellyn on sales. On the other hand, they underestimated the role of generalization and of justification in the law. Dewey had distinguished clearly between the “logic of inquiry” and the “logic of exposition,” between an argument’s source and its persuasiveness. Yet the realists often pointed to a judge’s psychological processes or social background as if they were demonstrating the irrelevance of her justifications or the speciousness of her claim to be applying rules.

Realism is especially inadequate if taken to be the comprehensive explanation or theory of the nature of law suggested by the definitional form of certain central realist slogans. Thus, realists constantly endorsed Holmes’s statement that “the prophecies of what the courts will do in fact . . . are what I mean by the law.” This remark can be accepted as a paradoxical emphasis on the individual discretion inherent in applying “open-textured” concepts to particular circumstances; accordingly, the exercise of

individual discretion becomes part of any adequate concept of law. But Holmes’s remark cannot be accepted if it is read as an assertion that the best understanding of legal reality derives from equating law with prediction. A predictive viewpoint obscures the role of legal rules as guides to conduct. As H. L. A. Hart said, “legal rules function as such in social life: they are *used* as rules not as descriptions of habits or predictions” (*The Concept of Law*, Oxford, 1961, pp. 134–135). If the normative character of legal rules were not generally accepted, our concept of law would be entirely different.

However, it may be that attempts, like that of the realists, to jolt accepted habits of thought must rely on paradox and exaggeration. Pierre-Joseph Proudhon said, “Property is theft,” knowing full well the immediate sense in which “property” is not “theft” at all. In jurisprudence the very distortion frequently produces the insight; we often learn more from a caricature than from a photograph.

See *Punishment; Responsibility, Moral and Legal*

## LEHRER, KEITH

(1936–)

Keith Lehrer was born January 10, 1936, in Minneapolis, Minnesota. He attended the University of Minnesota from 1953 to 1957, earning his BA in Philosophy magna cum laude. His teachers at Minnesota included Alan Donagan, John Hospers, Michael Scriven, Mary Shaw, May Brodbeck, Herbert Feigl, and Wilfred Sellers. Lehrer went on to earn his AM in 1959 and his PhD in 1960, both in philosophy, at Brown University, where his teachers included Roderick Chisholm, John Ladd, John Lenz, Stephan Körner, Vincent Thomas, Wesley Salmon, and Richard Taylor. Chisholm supervised Lehrer's master's thesis on epistemology, and Taylor supervised Lehrer's doctoral dissertation on free will. Chisholm's and Taylor's continuing support were not due to Lehrer's agreement with their positions: Lehrer was then and continues to be a coherence theorist in epistemology, whereas Chisholm was a foundationalist, and Lehrer has always endorsed compatibilism, whereas Taylor was a libertarian.

Lehrer is best known for his work on free will, theory of knowledge, rational consensus, and the philosophy of Thomas Reid. His earliest philosophical works clearly reflect the ordinary language and common sense approaches to philosophy that he learned first from Hospers at Minnesota, and then through the influence of Reid, partly gained indirectly from Reid's influence on both Chisholm and Taylor. Lehrer's first published article (1960) was a common sense defense of the claim that humans can know they have free will simply through introspection.

Despite his lifelong commitment to compatibilism, many of Lehrer's earliest works were critical of various analyses of freedom intended to defend that view—particularly hypothetical analyses of freedom (e.g., that S is free to do X just in case S would do X if S tries to do X). Lehrer's argument against such analyses is that the conditional might apply to S, but S might lack some advantage necessary for exemplifying the antecedent of the conditional. So, for example, it could be true that S would do X if S tried to do X, but because of some phobia or other disadvantage, S could never actually try to do X. One may thus have control over external circumstances, but not

have control over oneself, and such a disadvantage leaves one unfree.

His own first defenses of the compatibility of freedom and determinism were based upon a possible worlds analysis of freedom. His work in the late twentieth and early twenty-first centuries analyzes freedom in terms of a power preference that is a preference for having the preference structure one has concerning an action. To insure freedom, one must have that power preference because one prefers to have it. The preference for the preference structure must be the primary explanation of one's having it.

Lehrer is one of the best known proponents of a coherence theory of knowledge. On Lehrer's view, coherence consists in a cognitive system that is able to meet critical objections to the acceptance of a target proposition. Although his first analyses included a standard belief condition, Lehrer later argues that acceptance rather than belief should constitute the relevant condition, partly because the former involves a decision one makes. One's epistemic mission is to accept what is true and not to accept what is false. One cannot decide what to believe at a given moment; but one can decide what to accept in the pursuit of one's epistemic mission.

The ability of a background system to meet critical objections to the accepting of something one accepts provides personal justification. Lehrer first construed this background system as consisting only in states of acceptance designed to pursue the subject's epistemic mission; he expanded this view of the background system, which he later calls the "evaluation system," to include preferences and reasonings.

Much of Lehrer's earliest work in epistemology critiqued various attempts to solve the Gettier problem. The Gettier problem shows that one can have convincing justification of a true belief and yet not have knowledge because some part of the justification is false, where if that part were removed or replaced by the truth, one would no longer qualify as justified. Where such problems in justification exist, the justification is "defeated," and defeasibility theorists seek to solve the Gettier problem by formulating and explicating as a necessary condition the stipulation that one who knows has undefeated justification for what one knows. Defeasibility remains a central concern in Lehrer's most recent work in epistemology, *Theory of Knowledge* (2000), according to which knowledge is the product of true belief that is personally justified on the basis of coherence with the evaluation system, where such justification is undefeated. Undefeated justification, according to Lehrer, is a kind of justi-

fication that cannot be refuted by pointing out errors in the evaluation system (2000).

Lehrer has also offered a number of criticisms of recent “naturalistic” or externalist approaches to knowledge and justification, on the general ground that reliable cognitive mechanisms or ways of believing that track truth without cognitive self-evaluation are insufficient for knowledge. Lehrer’s development of this element of his epistemology derives from his interest in the philosophy of Thomas Reid. Lehrer noted within Reid’s system a metaprinciple according to which our faculties and the principles thereof are trustworthy. Lehrer applies this same principle to allow the knower to meet critical and skeptical objections, while also immunizing his own analysis of knowledge—despite its requirement for cognitive self-evaluation—against the KK-regress (namely, that one’s knowing requires knowing that one knows, that one knows that one knows one knows, and so on ad infinitum) (1990, 2000).

The theory of rational consensus, which Lehrer developed with Carl Wagner (1981), was an attempt to incorporate a social component into the theory of rationality—another echo of Reid’s common sense approach to philosophy. Social rationality, in Lehrer’s and Wagner’s theory, results from the evaluations people make of others, expressed mathematically as weights. They argue that under plausible conditions of evaluation social convergence would yield rational consensus. Lehrer went on to unify his work on justification and preference in *Self Trust* (1997), in which he sought to explain the trustworthiness of the self in terms of rationality, theoretical and practical as well as personal and social. In this and in his epistemology, Lehrer claims that complete explanation will contain a loop of the sort Lehrer first found in Reid’s philosophy. There is a fundamental choice, according to Lehrer, between starting with unexplained first principles or, instead, maximizing explanation by including a principle of trustworthiness, which explains both why people are justified in accepting everything else that they accept and also why people are justified in accepting the principle itself. The effectiveness of the explanation depends on the wider system of explanation as well, and not simply on the “keystone principle” of self-trust.

## LEIBNIZ, GOTTFRIED WILHELM (1646–1716)

The German polymath Gottfried Wilhelm Leibniz made significant contributions to philosophy, logic, mathematics, physics, jurisprudence, politics, the mechanical arts, and history. He worked as a diplomat, an engineer, an attorney, and a political advisor. He corresponded with queens and emperors and with the most eminent intellectuals of the age. Yet his reputation as a philosopher depends largely on texts that were unpublished at the time of his death, including some never intended for publication. Besides well-known works such as the *Discourse on Metaphysics*, *First Truths*, *New Essays*, and *Monadology*, there are thousands of pages of other texts, many of which are still unpublished. Interpreting these vast writings is a daunting task, best approached by attending closely to the historical and cultural context in which he

was working and by taking into consideration as many texts as possible. Against the background of Leibniz's long, complicated life, it is possible to trace the development of his philosophical views, from his earliest essays in Leipzig in the 1660s to his last letters written in Hanover fifty years later.

The sheer volume of Leibniz's writings, combined with the fact that some are published and some are not, can sometimes make citing Leibniz seem complicated. The standard edition of his works is *Gottfried Wilhelm Leibniz: Sämtliche Schriften und Briefe*, which was published by the Akademie Verlag in 1923. To simplify citations in this text, it is abbreviated throughout simply as "A," followed by series, volume, and page number (see "A" in the Abbreviations section of the Bibliography at the end of this essay for full publication information). When an English-language translation exists, it follows a colon at the end of the German-language information. In addition to the abbreviation for that primary work, other prominent texts on Leibniz's life and works have also been abbreviated in the in-text citations that appear throughout this essay—a list of those abbreviations and full publication information for every one of them is provided in the Abbreviations section at the very beginning of the Bibliography.

It should be noted that, in regard to Leibniz's philosophical texts, as of mid-2005, only those written up to June 1690 had been published; for texts written after that date that are referenced in this essay, the best available edition has been cited. Finally, works by Leibniz that are divided into short sections have been cited by section number instead of by page number.

## LIFE

Leibniz was born in the Lutheran city of Leipzig on July 1, 1646 to Friedrich Leibniz (1597–1652), professor of moral philosophy at the University of Leipzig and the son of a noblewoman and his third wife, Catharina Schmuck (1621–1664), the daughter of a celebrated jurist. An orphan, Schmuck was raised by Johann Hopner, professor of theology, as well as by Quirin Schacher, professor of law. Upon Friedrich's death in 1652, Schmuck committed herself to the education of her son and his sister, Anna Catharina (1648–1672). As a very young boy, Leibniz was given access to his father's library where by his own account he taught himself Latin and read poetry, history, theology, and some Aristotelian philosophy.

On graduating from the Nicolai School, Leibniz entered the University of Leipzig in April 1661, aged fourteen. He studied ancient languages and literature and

heard lectures in mathematics (mainly Euclid) and philosophy. Although the new mechanical philosophy of René Descartes, Thomas Hobbes, and Pierre Gassendi had not been embraced by the professors in Leipzig, there was a diverse intellectual culture available there. Johann Adam Scherzer (1628–1683), professor of philosophy, Hebrew, and theology, published on a wide range of topics, including Kabbalistic theology while Jakob Thomasius (1622–1684) promoted an eclectic mixture of Platonism, Aristotelianism, and other prominent historical schools. Thomasius was an unusually careful historian of philosophy, keen to distinguish between the true and false proposals of the various philosophical *sects*. As the father of Christian Thomasius, who (with Christian Wolff) is often credited as founding the German enlightenment, Jakob Thomasius occupies an important place in the development of German philosophy. Thomasius supervised Leibniz's bachelor's thesis titled *Disputatio metaphysica de principio individui* (Metaphysical Disputation on the Principle of Individuation), which Leibniz defended and published in 1663. The thesis argues for a monadic account of substantial individuation, a position that prefigures his mature views.

Leibniz spent the summer of 1663 at the University of Jena studying under Erhard Weigel (1625–1699), professor of mathematics. Weigel was more progressive than the professors at Leipzig and included mechanical physics within his eclectic mixture, combining Euclid, Aristotle, and the *new philosophers* in an attempt to construct the true philosophy. He returned to Leipzig in October 1663 and received his bachelor of law degree in 1665 under professors Schacher and Bartholomäus Schwendendörffer. In 1666, he published *Dissertatio de arte combinatoria* (Dissertation on the Combinatorial Arts). It contains his first thoughts on the universal characteristic and related logical issues. He planned to pursue legal studies at Leipzig but was refused admission (probably because of his age) and went instead to the University of Altdorf, near Nuremberg, where he quickly earned a doctorate. His dissertation *Disputatio de casibus perplexis in jure* (Disputation on Difficult Cases in Law, 1668) was so well written and defended that the Altdorf faculty immediately offered him a professorship.

Leibniz declined the Altdorf professorship and chose, instead, a life of public service. In Mainz, he impressed Baron Johann Christian von Boineburg (1622–1672), a pious Catholic, distinguished diplomat, and minister to the archbishop of Mainz, Elector Johann Philipp von Schönborn (1605–1673). Boineburg became Leibniz's patron and employed him as an assistant, attor-

ney, librarian, and foreign advisor. In this last capacity, Leibniz produced a lengthy work supporting Schönborn's candidate for the Polish throne. The Catholic Boineburg encouraged the Lutheran Leibniz to pursue ecumenical and conciliatory projects, and he began a project, *Demonstrationes Catholicae* (*Catholic Demonstrations*), aimed at devising a metaphysics consistent with Catholic and Lutheran doctrines. He worked on the *Catholic Demonstrations* between 1668–1671 and returned to it in 1679. Although never completed, it contains his earliest essays on central metaphysical topics.

Besides pursuing peace in politics and religion, the young Leibniz was committed to philosophical peace. In an effort to offer a conciliatory method in philosophy, he prepared a new edition of Marius Nizolius' (1498–1576) 1553 work, *De veris principiis, et vera ratione philosophandi contra pseudophilosophos* (*On true principles, and the true method of philosophizing against the false philosophers*). Also, between 1669 and 1671, he composed a series of notes titled *Elementa juris naturalis* (*Elements of Natural Law*), in which he discusses theology, metaphysics, and ethics. These notes cover a wide range of topics, including divine and human justice, knowledge, and universal harmony. At this time he began a correspondence with the Duke of Brunswick Johann Friedrich (1652–1679), presenting his views about the souls or *vital* principles in nature, to which he attached important theological essays on the immortality of the soul and the resurrection of the body.

In 1671 Leibniz published two related works that constitute his first extended account of the laws of motion and their metaphysical foundations. The first, the *Hypothesis physica nova* (*New Physical Hypothesis*), subtitled *Theoria motus concreti* (*Theory of Concrete Motion*), he dedicated to the Royal Society of London; the second, the *Theoria motus abstracti* (*Theory of Abstract Motion*), he dedicated to the French Academy of Sciences. Together these works, which employ the Hobbesian notion of *conatus* along with the indivisibles of authors such as Bonaventura Cavalieri (c. 1598–1647), propose a physical system, including a creation story and laws of collision, which relies on the notion of momentary minds. Thus, by 1671 he had already begun to think of minds as the only source of motion and activity in the world; minds in non-human substances are momentary while human minds persist and have memory. This attempt to combine an original account of mind with a Hobbesian notion of *conatus* reveals his conciliatory tendencies as well as his capacity to engage in contemporary discussions in physics.

In 1671 Leibniz and Boineburg devised an elaborate plan to divert a pending European war. With secret papers in hand, Leibniz traveled to Paris in March 1672 to meet with a representative of King Louis XIV but arrived too late. Despite this failed diplomatic undertaking, he remained in Paris, at first to promote other political plans of his mentor and then, upon Boineburg's sudden death at the end of 1672, to pursue philosophical peace. He stayed in Paris until 1676 and struggled to stay longer, arguing that the pursuit of science in the service of humanity could be better achieved there than in Hanover, where the Duke of Brunswick had recently employed him.

Leibniz's four years in Paris were enormously productive. In the fall of 1672, he met the Dutch mathematician Christiaan Huygens (1629–1695) who immediately recognized the young man's talent and guided his mathematical studies. Although his education had not acquainted him with recent developments in mathematics, he devoted himself to study and by the fall of 1675 had laid the foundations of his calculus. During his lifetime he suffered from accusations that he had stolen the insights that led to his discovery of the differential and integral calculus from Isaac Newton. But twentieth-century historians of science exonerated him from these charges, showing that he arrived at the calculus independently of Newton.

In early 1673 Leibniz traveled briefly to England on a political mission and met mathematicians and natural philosophers, including Robert Hooke (1635–1703), Robert Boyle, and Henry Oldenburg (1619–1677), secretary of the Royal Society. Back in Paris, he finished a lengthy dialogue, *Confessio Philosophi* (*Philosopher's Confession*), in which he discusses the problem of evil, a topic that would engage him until his death. He also wrote an essay “De vera methodo philosophiae et theologiae ac de natura corporis” (“On the True Method in Philosophy and Theology and on the Nature of Body,” in which he restates his fundamental methodological concerns and insists that neither mechanical physics nor mathematics speaks directly to what is most important, namely, the good of the soul and the truths of theology. In 1675 he designed and demonstrated a calculating machine and befriended the young mathematician Ehrenfried Walther von Tschirnhaus, who introduced him to the philosophy of Benedict (Baruch) de Spinoza. At the same time he began work on a group of notes, given the title *De Summa Rerum* (*On the Greatest of Things*), in which he discusses a diverse group of theological and metaphysical topics.

Partly due to prejudices against his religion and nationality, Leibniz failed to attain appropriate employment in Paris, and in 1676 he reluctantly accepted an offer from Johann Friedrich to serve as librarian and adviser at the court of Hanover. In October he traveled from Paris to London and Holland before proceeding to Hanover where he took up residency in December. During his journey he composed a dialogue, *Pacidius Philalethi Prima de Motu Philosophia* (Pacidius to Philalethes: A First Philosophy of Motion), which concerns the problem of the continuum and offers an account of motion. In London he met with Oldenburg again and also John Collins (1624–1683), mathematician and librarian of the Royal Society, who showed him some of Newton's papers. In Holland he met with prominent Dutch mathematicians and scientists, including the microscopists Jan Swammerdam (1637–1680) and Antoni van Leeuwenhoek (1632–1723). He talked at length with Spinoza and possibly saw a draft of Spinoza's *Ethics*.

Settled in Hanover Leibniz continued to work in logic, metaphysics, theology, and mathematics. He met visiting scholars and theologians (including Nicolaus Steno [1631–1686]) and wrote a dialogue on free will, *Dialogue entre Poliandre and Théophile*. He took notes on Spinoza's *Ethics*, then newly published, corresponded with Nicolas Malebranche on metaphysics, and returned to the *Catholic Demonstrations* and his work on the universal characteristic. He studied chemistry and made detailed proposals to Johann Friedrich about administrative matters, including the expansion of mining in the Harz mountains. Besides technical tasks involved with the mines, he was much occupied in 1678–1679 with logical topics. He composed a series of highly original notes, given the title *Calculus Universalis* (*Universal Calculus*, in which he tries to formulate a logical calculus. Underlying this work is again his interest in methodology as a means of leading people to the truth and thereby effecting peace. Inspired by the multivolume *Encyclopedia* by Johann Heinrich Alsted (1588–1638), he planned his own encyclopedia project. Also during this time he made a breakthrough in his work on dynamics, defending the notion of force as against the Cartesian principle of conserved motion.

The sudden death of Johann Friedrich and the succession of his brother, Ernst August (1629–1698), in 1680, marked the end of this period of intense productivity. Leibniz remained on good terms with the duke and developed a close friendship with the duke's wife, Sophie, Duchess of Brunswick (1613–1714), with whom he cor-

responded on political, theological, and philosophical topics. The new duke, who would later become elector, encouraged Leibniz's technical and political schemes but was less receptive to academic matters and left the philosopher much less time to develop his own projects. Leibniz was assigned the burdensome task of compiling a history of the House of Brunswick, with the aim of establishing descent from the wealthy Italian house of Este. This project occupied him until his death (by which time, for all his efforts, he had only reached the year 1005).

Between 1680 and 1686 Leibniz worked primarily on logic and on the Harz mining project designing windmills and other equipment. When Leipzig professor Otto Mencke (1644–1707) began publishing a scholarly journal the *Acta Eruditorum*, with the aim of introducing new ideas to German scholars, Leibniz applauded the project and became a frequent contributor on scientific topics. During this time he began another attempt to formulate a logical calculus and renewed his work on the reconciliation of Protestantism and Catholicism. In that context he began a correspondence with Landgrave Ernst von Hessen-Rheinfels (1623–1699), a Catholic eager to promote religious peace.

Caught in a snowstorm for a few days in the Harz mountains in early 1686, Leibniz took advantage of the free time to compose one of his most famous works, the *Discours de métaphysique* (*Discourse on Metaphysics*). It represents his first attempt to summarize the main ideas of his philosophy. He asked Landgrave Ernst to send a synopsis to Antoine Arnauld, and thus began one of the most interesting philosophical correspondences of the seventeenth, or any other, century. Arnauld's criticisms forced Leibniz to explain and expand upon some of his most fundamental ideas.

Leibniz was disappointed when the duke abandoned the Harz mining project but immediately began planning a trip to research the history of the House of Brunswick. In October 1687 he set out on an extended tour of the southern German states, Austria, and Italy. His official duty was to research family history; his personal desire, encouraged by Landgrave Ernst, was to promote religious and political peace. He visited public archives and personal libraries and talked with politicians, monks, and cardinals. During his residence in Vienna, he met the Austrian emperor, to whom he recommended, among other things, the reorganization of the economy, the formation of a general research library, and the establishment of an insurance fund; he worked on proposals for an Imperial College of History; for reforming the coinage of Austria, Brunswick, and Saxony; and for lighting the streets of the

city. And he wrote an important paper on motion later published in the *Acta Eruditorum*.

Leibniz spent a year in Italy traveling as far south as Naples and meeting with prominent intellectuals along the way. In Rome (April–November 1689), he made contact with leading Italian scientists, Jesuits (including Claudio Grimaldi [1638–1712], who had lived in China and with whom Leibniz corresponded), and Jansenists. Visits to the Physical-Mathematical Academy led to a treatise on dynamics, *Dynamica de potentia et legibus naturae corporeae* (Dynamics: Concerning the force and laws of natural bodies), which has two parts, one on abstract and the other on concrete dynamics. In Modena he arranged a marriage between the House of Modena and one of Duke Friedrich's daughters. In Venice he met the scientist and Jesuit Michel Angelo Fardella (1650–1708), with whom he later corresponded on philosophical topics.

Before leaving Italy Leibniz wrote a long (last) letter to Arnauld in which he develops further details of his metaphysics. At about the same time, he composed one of his most well-known texts, *Primaes Veritates* (*First Truths*). Written on Italian paper, the paper (given the title *Principia Logico-Metaphysica* by the academy editors) dates from the time during—or soon after—his trip to Italy. The four-page essay is a neat summary of his most fundamental philosophical principles, which are outlined in a form interestingly different from previous presentations. Leaving Venice in March 1690, he traveled through Vienna, Prague, Leipzig, and other cities before returning to Hanover. In Vienna he wrote an important paper on motion and gravity titled *De causa gravitatis, et defensio sententiae auctoris de veris naturae legibus contra cartesianos* (On the cause of gravity), which was published in the *Acta Eruditorum* in May. When he arrived back in June 1690, he had been away for more than two and a half years.

Upon his return Leibniz felt the need to justify his lengthy and relatively expensive trip and so committed a good deal of time to his history of the House of Brunswick. In 1690 he became director of the ducal library in Wolfenbüttel, a position that he held for the rest of his life. During the early 1690s he maintained his close relationship with Sophie, by this time Electress of Hanover, published often (especially on mathematical and dynamical topics) in the German *Acta Eruditorum* and the French *Journal des Sçavans*, continued old correspondences, and began new ones (for example, with Johann Bernoulli [1667–1748]). His relations with members of the Royal Society, which had never been unprob-

lematic, took an unfortunate turn when he was accused of using Newton's work as the basis for his own calculus. In March 1693 he wrote directly to Newton about the topic.

In the 1690s Leibniz exchanged several letters with Paul Pellisson-Fontanier (1624–1693), which were then shared with interested parties, including Sophie and her Catholic sister, Marie de Brinon. These letters addressed differences between Catholic and Protestant theology and the possibility of unification among the churches. The well-known physician, Kabbalist, and Quaker sympathizer, Francis Mercury van Helmont (1614–1698) visited Hanover and spent several days lecturing Leibniz and Sophie about his views. Becoming more and more fascinated with reports from Jesuits in China about the science and mathematics of that culture, Leibniz published *Novissima Sinica* (Latest news from China) in 1697, which is an edition of letters and reports from the Jesuit's mission there. For Leibniz the reports from China supported his assumption that there is an underlying truth that all people seek and that could be glimpsed, regardless of religion.

At each stage of his life, Leibniz worked on many diverse projects and wrote thousands of notes on philosophy, mathematics, science, and theology. As an intellect he was in constant motion. It is therefore striking that he published so little. After the texts of 1670–1671, he did not publish a general account of his views until 1695 when his *Système nouveau de la nature et des la communication de substances, aussi bien que de l'union qu'il y a entre l'âme et le corps* (New system of nature), a relatively brief account of a part of his metaphysics, appeared in the French *Journal des Savants*. This led to discussions with prominent Cartesians and others, including Simon Foucher and Basnage de Beauval (1692–1708).

In 1695 Leibniz was promoted to privy counselor of justice, a high-ranking position at court. However, he was not entirely content, complaining that he had little time for new ideas and projects and that, apart from Electress Sophie, there was no one with whom he could discuss intellectual matters. Ernst August died in early 1698 and was succeeded by his eldest son, Georg Ludwig (1660–1727) (later George I of England). Georg Ludwig had little patience either for Leibniz's slow progress on the history of the House of Brunswick or for his other *invisible* projects, and Leibniz received less financial support and freedom of movement. But his friendship with Sophie continued, and his relations with her daughter, Sophie Charlotte, Electress of Brandenburg (and soon to be Queen of Prussia) also became close. Sophie Charlotte

often asked Leibniz to act on her behalf, and she supported him in his successful attempt to set up the Berlin Society of Sciences in 1700. As founding president, he wrote its charter.

At this point Leibniz was ready to publish further details of his system of *preestablished harmony*. One of the most important accounts, *De Ipsa Natura* (On Nature Itself), appeared in *Acta Eruditorum* in 1698 and contains his first use of the term *monad*. These publications led to important intellectual exchanges with Pierre Bayle, Burchard de Volder (1643–1709), Lady Damaris Masham (1658–1708), Bernoulli, Bernard le Bovier de Fontenelle, Bartholomew des Bosses (1668–1728), Wolff (who became a kind of disciple), and others.

In the final years of the seventeenth century, Leibniz engaged again in controversy over the invention of the calculus. He was also drawn into secret diplomacy with the English court over the royal succession. Sophie Charlotte and he frequently conversed and exchanged letters about political and philosophical matters. After her sudden death in 1705, he wrote a memorial on topics they had discussed, which subsequently became his *Essais de Théodicée* (*Theodicy*), dedicated to her. Published in 1710, the *Theodicy* is the longest and most prominent publication of his life. In it he attempts to reconcile the goodness of God, the freedom of human kind, and the origin of evil. Its central claim, that this is the best of all possible worlds, was subsequently ridiculed by François-Marie Arouet de Voltaire in *Candide*.

By 1705 Georg Ludwig had lost all patience with Leibniz and forbade him to leave Hanover without permission until the history of the House of Brunswick was complete. Besides visits to nearby Wolfenbüttel, he spent much of his time over the next few years on the history and political relations among the courts in England, Hanover, and Brandenburg. But despite these duties, he began a study of John Locke's *Essay concerning Human Understanding* and wrote essays, some of which he published, on philosophy. As a result of his critical respect for Locke, he composed a lengthy dialogue between a Lockean and a Leibnizian but chose not to publish this text, *Nouveaux essais sur l'entendement humain* (New Essays on Human Understanding) because Locke died in 1704, around the time the work was finished.

In his last years Leibniz continued as librarian of Wolfenbüttel, political adviser, and historian. In 1711 he met Russian Czar Peter the Great (1672–1725) who wanted to engage him on legal and scientific matters. In 1713 Leibniz traveled to Vienna where the Austrian emperor appointed him imperial privy counselor and

agreed to create a Society of Sciences. From Vienna he counseled friends in Hanover and Wolfenbüttel though dislike for him at court had increased. When Georg Ludwig became King George I of England in 1714, Leibniz returned to Hanover in hopes of seeing his employer. They missed one another, but the king left instructions insisting that the history of the House of Brunswick be finished. Despite these pressures and encroaching ill health, he began new correspondences—with Nicolas Remond in Paris and Samuel Clarke, an English Newtonian. He also wrote *Principes de la nature et de la grace, fondés en raison* (The Principles of nature and grace, based on reason); the *Discours sur la théologie naturelle des Chinois* (Discourse on the natural theology of the Chinese), in which he shows the connections between Chinese thought and his own *true* philosophy; and the *Monadology*, perhaps his most famous work, providing a summary of the basic tenets of his later philosophy.

Leibniz suffered from gout and by 1714 was severely affected. In the last months of his life, he developed sores on his right leg. Distrusting physicians he refused to see a doctor when he suffered an attack of kidney stones. Working constantly he died in bed on 14 November 1716. By this time he was so out of favor with the court that only a handful of people attended his funeral. Because few of his works were published during his lifetime, it was only in the later part of the eighteenth-century that the extent of his genius began to be understood and acknowledged. It would be left to twentieth-century scholars to uncover the extraordinary breadth of his contributions in physics, mathematics, logic, theology, and philosophy.

## PHILOSOPHICAL CORPUS

Among the writings of great early modern thinkers, Leibniz's are unusually problematic. Descartes, Galileo, Spinoza, Hobbes, Malebranche all produced brilliant explications of their philosophies. But there is no single exposition of Leibniz's metaphysics replete with extended arguments and details. He published little during his lifetime and no published text (e.g., *A New System of Nature*, the *Theodicy*) provides a thorough-going account of his philosophy. Although there are a number of identifiable *main* texts, it remains unclear how to treat them since they differ noticeably from each other and were written over many years.

Leibniz wrote more pages—in Latin, French, and German—than most scholars can read in a lifetime. Stored in Hanover after his death, his papers were unorganized, unedited, and undated. The main part of his philosophical corpus has not been available in a standard

edition. The early editions of his philosophical work—a late eighteenth-century edition by L. Dutens and a late nineteenth-century collection by C. I. Gerhardt—are incomplete and sometimes inaccurate. The Prussian Academy of Science (now the German Academy of Science) began to publish the standard edition of his papers in 1923, but it has taken decades to cover even the main works in philosophy. The publication of the remainder is expected to take until 2050. It is surely difficult to acquire a broad understanding of his writings when only a small selection is available.

Leibniz's philosophical writings pose additional problems. First, many of them are hastily written personal notes, often both incomplete and undated. As he himself wrote about his papers: "Instead of treasure ... you will only find ashes; instead of elaborate works, a few sheets of paper and some poorly expressed vestiges of hasty reflections, which were only saved for the sake of my memory" (A VI i 533). Second, even in the publications and letters sent to the great philosophers of Europe, he had specific methodological reasons for not being forthright about his views: His goal was to avoid preaching in an attempt to engage his reader. By such means he hoped to nudge the wayward soul toward the truth. In a frank moment in 1676 he writes: "A metaphysics should be written with accurate definitions and demonstrations, but nothing should be demonstrated in it apart from that which does not clash too much with received opinions. For in that way this metaphysics can be accepted; and once it has been approved then, if people examine it more deeply later, they themselves will draw the necessary consequences" (A VI iii 573–574: Pk 93). Finally, given his astonishing erudition, it is difficult to reconstruct the conceptual framework of his writings. Not only did he use major parts of the history of philosophy without citation or explanation, he thought that it was a *good thing* to combine ideas taken from the great philosophical systems. One of the main reasons that it is so difficult for us to recognize the borrowed doctrines and transformed assumptions in his writings is that he made such abundant use of the entire history of philosophy as it was conceived in the seventeenth century.

Due to the difficulties posed by Leibniz's writings, texts such as the *Discourse on Metaphysics*, *First Truths*, *New System*, *New Essays*, and *Monadology*—all of which suited twentieth-century philosophical tastes—became his canonical writings. As important as these writings are, they do not represent the extraordinary range and quirky diversity of his ideas. He is rarely explicit about the precise relations among his ideas, but he is clear about the

fact that they are tightly connected. At the end of his life, he insists: "My principles are such that they can hardly be torn apart ... whoever knows one well knows them all" (G II 412: L 599).

In an attempt to reveal the breadth of Leibniz's philosophical system and the connections among core doctrines, this article cites a diverse group of texts selected from all the main periods of his life. He borrowed ideas from the whole history of philosophy, and so before considering some of his philosophical ideas, we will situate them in their proper historical context.

## METHODOLOGY AND INTELLECTUAL HARMONY

The early Renaissance philosopher Giovanni Pico della Mirandola, formulates in his *On the Dignity of Man* (1486) one of the defining statements of the conciliatory methodology of many humanist thinkers. Pico recommends that the seeker of truth study all the masters of philosophy. Once the truths in each philosophical tradition are discovered, they will be combined into a comprehensive philosophy. One of the main points of Pico's project is to show that a *concord* can be forged between the philosophies of Plato and Aristotle. For intellectual conciliators such as Pico, the doctrines of the prominent philosophical traditions, despite their apparent differences, can be made to form a coherent philosophical system.

In the aftermath of the Thirty Years War, whose battles were fought mostly on German soil, this methodology of peace was extremely attractive, especially to German thinkers, many of whom had witnessed the devastation and horrors of the war firsthand. As a young man Leibniz committed himself to his own form of conciliatory eclecticism. Like Pico he thought that the fundamental truths were (mostly) those offered by the illustrious ancient thinkers. Some of his basic metaphysical beliefs were taken directly from the Aristotelian, Platonist, and mechanical philosophies: that a substance is something wholly self-sufficient, that each creature is an emanation of God's essence, and that all corporeal features are to be explained mechanically. But he also went beyond Pico in his commitment to a philosophy that is consistent with specific Christian doctrines, such as those of the Eucharist and the resurrection of the body. His grand philosophical system is the result of the clever interweaving of ancient and modern assumptions.

In 1671 Leibniz published an edition of a text by the sixteenth-century humanist Mario Nizolio (1488–1567). He wrote a lengthy introduction to Nizolio's 1553 book

*On the True Principles and the True Method of Philosophy, Against the Pseudo-philosophers.* Both Nizolio's text and Leibniz's introduction discuss the proper way of philosophizing. It is significant that Leibniz attached to his introduction a slightly revised version of his April 1669 letter to Jakob Thomasius. The letter thereby became the young man's first published text on a contemporary metaphysical topic. Instead of being yet another philosopher "lusting for novelty," Leibniz seeks to find the "interconnections among doctrines" (A VI ii 426). He presents what he calls a "reformed philosophy," a philosophy that combines the "rule" of the new mechanical physics and the metaphysics of Aristotle (A VI II 434: L 94). He focuses on corporeal substances and reforms Aristotle's notions of substantial form and matter so that they accommodate the mechanical physics. By demoting the mechanical notion of matter as extended stuff to Aristotelian prime matter, he cleverly constructs a theory of substance that has the structure of the Aristotelian notion and yet is consistent with mechanical explanations in physics. He happily concludes that by such means, the mechanical philosophy "can be reconciled with Aristotle's" (A VI ii 435: L 95). The details of his views about substance would change over the years, but the basic structure of this theory of substance, developed as a synthesis of Aristotelianism and mechanism, would remain the same.

In his *New Essays*, written in response to Locke in the early years of the eighteenth century, Leibniz reflects on the methodology that produced his philosophy: "This system appears to unite Plato with Democritus, Aristotle with Descartes, the scholastics with the moderns, theology and morality with reason. It seems to take the best from all quarters and then goes further than anyone has done before" (A VI vi 71–73). His concern with intellectual harmony emerges also in his concern to engage his readers and interlocutors so as to enlist them in his march toward truth. In a letter of March 1678, he explains:

I am concerned, as are all who wish to hold a middle ground, not to seem too much inclined toward either of the two opposed adversaries. Whenever I discuss matters with the Cartesians ... I extol Aristotle where he deserves it and undertake a defense of the ancient philosophy, because I see that many Cartesians read their one master only ... and thus unwisely impose limits on their own ability. ... I think that the two philosophies should be combined and that where the old leaves off, the new should begin." (A II i 402: L 190)

For Leibniz the true metaphysics will be consistent with Christian doctrine and constructed from the underlying truths in the great philosophical systems. An underappreciated aspect of his brilliance is his ability to gather ideas from different philosophical sources and make them his own.

## GOD AND CREATION

Like other prominent thinkers of the seventeenth century, Leibniz believed in a perfectly good Supreme Being who created and maintained the world and whose existence could be proven. He sometimes employed versions of the cosmological argument for God's existence. For example, in the *Monadology* (1714), he argues for God a posteriori based on the harmonized diversity of the world and the fact that there are contingent beings whose "final or sufficient reason" must be in a "necessary being" (§39, §45). But his favorite argument is an original version of the ontological argument, which is critical of Descartes's version and based on the mere possibility of God: "Since nothing can prevent the possibility of what is without limits, without negation, and consequently without contradiction, this by itself is sufficient for us to know the existence of God a priori" (§45).

Like many of his contemporaries, Leibniz owed a number of his assumptions about God as creator of the world to an ancient (mostly Platonist) tradition. From prominent professors at the University of Leipzig, he acquired a solid education in Platonism. The version of this ancient philosophical "sect" taught in Leipzig was one inspired by the third-century Platonist, Plotinus (c. 204–270) and by Jewish Kabbalism. Many of his most fundamental assumptions about knowledge, mind, plenitude, the nature of creation, and the relations among substances are rooted in this tradition. Two assumptions that he embraced as a young man are as follows:

**GOD AND EMANATION.** There is an ultimately good, perfectly self-sufficient, and thoroughly unified Supreme Being on which everything else depends and which itself depends on nothing. God's mind contains a number of Ideas or attributes (say, the Idea of Justice), which are the perfect essences of things (these are roughly based on Plato's theory of Ideas) and which are used as models for created things. The Idea or attribute of God is emanated to a creature in such a way that neither God nor God's attribute is depleted in any way while the creature acquires the attribute, though in an inferior manner. The emanative process is continual so that a creature instantiates a divine attribute if and only if God emanates the

attribute to the creature. For many Platonists, a corollary of this causal theory of emanation is that every product of the Supreme Being contains all the attributes (and hence the essence) of God though the product instantiates each of those attributes in a manner inferior to the way in which they exist in the Supreme Being. Justice as conceived by God is perfect; justice as instantiated by Socrates is not. Leibniz summarizes the position in §14 of the *Discourse on Metaphysics*: “It is evident that created substances depend upon God, who preserves them and who even produces them continually by a kind of emanation.”

**PLENITUDE AND SYMPATHY.** The divine essence is emanated not just to each creature but to the whole of creation. The principle of plenitude develops from the idea that the more of the divine essence in the world—and hence of being and goodness—the better. Although the principle of plenitude suggests that there will be as much diverse being as possible (the more being, the better the world), this diversity of being must also be properly unified (the more unity, the better the world). One of the results of this unity among the parts of the world is a cosmic sympathy. Here the idea is that each part of the world is *in sympathy* with all the others. In other words, the principle of plenitude was supposed to imply that God fills creation with as much being as possible and unifies those diverse beings as much as possible. Such a diverse and unified world was supposed to engender wonder, delight, and awe in human observers. In the *Monadology*, he agrees with the ancient philosopher Hippocrates who claimed that all things are in sympathy with one another: everything “is affected by anything that happens in the universe, to such an extent that he who sees all can read in each thing what happens everywhere, and even what has happened or what will happen, by observing in the present what is remote in time as well as in space” (§61).

These ancient Platonist assumptions about emanation, plenitude, and sympathy inform much of Leibniz’s thinking about the world. They inspire his theory of universal harmony, many of his views about mind, his account of knowledge, his solution to the problem of evil, and his views about the mirroring and expressing of substance. In this section, we consider the core doctrines closely related to these Platonist assumptions. As we will see, Leibniz remains committed to these doctrines throughout his philosophical career.

**UNIVERSAL HARMONY.** Leibniz first articulates the doctrine of universal harmony in a series of notes titled

*Elements of Natural Law*, written between 1668 and 1671. As he summarizes the idea for Arnauld in 1671: “I define ... harmony as diversity compensated by identity” (A II i 173–174: L 150). By the time he wrote the *Discourse on Metaphysics* in 1686, he had come to formulate the doctrine in terms of hypotheses though the underlying idea is still the same. In §6 of the *Discourse*, he explains: “God has chosen the most perfect world, that is, the one which is at the same time the simplest in hypotheses and the richest in phenomena.” According to Leibniz, the single, unified, and perfect Supreme Being freely chooses to emanate the divine attributes to creatures; God remains transcendent while all creatures become an imperfect instantiation of God’s attributes. Because God emanates the divine essence to all its products, he describes God as the reason (*ratio*) of the world and the one (*unum*) in it.

Universal harmony entails that God relates to the world and to each creature in it in two ways. God is the multiplicity in the world insofar as the divine essence is variously manifested in the vast diversity of creatures and in the diversity of the perceptions of each creature, but God is also the unity insofar as each created thing is a unified instantiation of the divine essence (although a manifestation of the essence far inferior to that of God) and therefore related to and reflective of all the others. The world is full of various perceptions of the world or *phenomena* because the world contains an infinity of different expressions of the divine essence. Leibniz’s notion of universal harmony forms the basis for his mature theory of pre-established harmony.

**PLENITUDE, DIFFERENCE, AND PRINCIPLE OF THE IDENTITY OF INDISCERNIBLES.** From 1676 on Leibniz is increasingly explicit about the significance of the principle of plenitude. In a series of notes written in Paris titled *On the Greatest of Things*, he writes: “I take as a principle ... that the greatest amount of essence that can exist does exist” (A VI iii 472: Pk 21). He never wavers from this commitment to plenitude. In *On the Ultimate Origination of Things* of 1697, he explains that God is the *reason*, or source, of things and argues that “there is a certain urge for existence or (so to speak) a straining toward existence in possible things or in the possibility of essence itself; in a word essence in and of itself strives for existence” (G VIII 303: AG 150). For Leibniz, the world is not just very full, it is as full of being as it can possibly be, consistent with harmony. As for his contemporaries Spinoza and Anne Conway, infinity is for Leibniz a mark of the fullness of being. Whereas Spinoza assigns God or nature an infinity of attributes, both Conway and Leibniz make each portion of the world infinitely full. In 1676 he claims

that every part of the world, regardless of how small, “contains an infinity of creatures,” which is itself a kind of “world” (A VI iii 474: Pk 25). He emphasizes the same point later in *First Truths* (1689): “Every particle of the universe contains a world of an infinity of creatures” (VI iv [B] 1647–1648: AG 34). For Leibniz there is an aesthetic aspect to this elaborate harmony among the infinity of creatures. As he puts the point in the *Monadology*:

the author of nature has been able to practice this divine and infinitely marvelous art, because each portion of matter is not only divisible to infinity, as the ancients have recognized, but is also actually subdivided without end, each part divided into parts ...; otherwise, it would be impossible for each portion of matter to express the whole universe” (§65).

Nor is Leibniz content merely to fill the world with being. He argues that in order to contribute to the world’s diversity, each created thing must be essentially distinct from every other. One of his most famous principles, the principle of the identity of indiscernibles, demands that no two substances are exactly alike. He writes in *Discourse*: “It is not true that two substances can resemble each other completely and differ only in number” (§9). Although he is not explicit about the importance of the principle until the late 1680s and then formulates it in a variety of ways, the basic idea is straightforward enough: There is always more than a mere numerical difference between substances. Two eggs might seem perfectly similar but they will not differ merely numerically; there will always be something true of one egg that is not true of the other. In *First Truths* he argues: “In nature, there cannot be two individual things that differ in number alone. For it certainly must be possible to explain why they are different, and that explanation must derive from some difference they contain” (A VI iv [B] 1645: AG 32). As he puts it in the *Monadology*: “It is also necessary that each monad be different from each other. For there are never two beings in nature that are perfectly alike, two beings in which it is not possible to discover an internal difference” (§9).

What the principle of the identity of indiscernibles claims is fairly clear; why he wanted to make such a claim is less so. His commitment to the principle of plenitude and theory of emanation offers insight into his underlying motivation. For Leibniz, as for many theists, the goodness of the world is a function of the diversity of beings as well as the order among them. Given that each creature contains the divine essence, the world will be better if it is as full of diverse emanations of the divine

nature as is consistent with unity and harmony. His principle of the identity of indiscernibles pushes this intuition to its logical extreme: By demanding that no two substances (that is, no two emanations of the divine essence) be the same, he thereby increases the amount of diversity in the world. The principle of the identity of indiscernibles is a neat way of insisting on difference of the required sort.

**MIRRORS AND EXPRESSIONS.** The image of the mind as a mirror is a permanent fixture of Leibniz’s mature thought. He first develops this idea in the *Elements of Natural Law* (1668–1671). Consider the following passage: “Since every mind is like a mirror, there will be one mirror in our mind, another in other minds. Thus, if there are many mirrors, that is, many minds recognizing our goods, there will be a greater light, the mirrors blending the light not only in the [individual] eye but also among each other. The gathered splendor produces glory” (A VI i 464: L 137). By such means, he goes beyond the plenitude and sympathy of his Platonist predecessors. He does not just maximize creatures and the assumed sympathetic relations among them, he heightens their connections by making each substance a mirror of all the others because each mind is (unconsciously) aware of all the others.

In the notes written in Paris in 1676, he develops his growing commitment to plenitude in a number of directions. For Leibniz, in *On the Greatest of Things*, each mind eternally mirrors the entirety of the world, and each does so from its own perspective. That is, consistent with the principle of the identity of indiscernibles, no two substances mirror the world from the same perspective. To elucidate his point he offers an analogy that he will use for the rest of his philosophical career: In the same way that travelers approaching a town from different directions see the town from different perspectives, so each mind approaches the world from a different perspective. For Leibniz it is important that each mind has a unique view of the world for “in this way a wonderful variety arises” (A VI iii 524: Pk 85). As he summarizes the point in *On the Greatest of Things* in 1676: “A most perfect being is one that contains the most. Such a being is capable of ideas and thoughts, for this multiplies the varieties of things, like a mirror” (A VI iii 475: Pk 29).

Forty years later Leibniz sets out the same claims, employing the same analogies, in the *Monadology*: “This interconnection or accommodation of all created things to each other, and each to all the others, brings it about that each simple substance has relations that express all

the others, and consequently, that each simple substance is a perpetual, living mirror of the universe” (§56).

Just as the same city viewed from different directions appears entirely different and, as it were, multiplied perspectively, in just the same way it happens that, because of the infinite multitude of simple substances, there are, as it were, just as many different universes, which are, nevertheless, only perspectives on a single one, corresponding to the different points of view of each monad. ... And this is the way of obtaining as much variety as possible, but with the greatest order possible, that is, it is the way of obtaining as much perfection as possible. (§57–58)

As these quotations suggest, there are close connections between the mirroring activity of minds and Leibniz’s mature doctrine of expression. In various texts and in various ways, he claims that each substance expresses God, each substance expresses the world, and each substance expresses every other substance. After years of analysis of the texts, scholars have remained unclear about the implications and interconnections of these claims and about how exactly the doctrine of expression relates to the idea of minds as mirrors. The 1676 Paris notes, *On the Greatest of Things*, help solve some of the most recalcitrant problems by revealing the underlying motivation behind the doctrine. Each substance is an emanation of God’s essence, and in this sense each shares the same essence. Each emanation will differ from every other by *expressing* the divine essence differently: “The essence of all things is the same,” and they differ “only in the manner of their expression” (A VI iii 573: Pk 95). To explain his point he compares the essence of God to a number that can be expressed in an infinity of ways, each of which is a more or less clear expression of the essence. For the number 6, whether the expression is  $3+3$ ,  $3\times 2$ , or  $4+2$ , each is an expression of the same thing although “no one can doubt that the one expression differs from the other” (A VI iii 518: Pk 77). In the same way that the number 6 may be thought to contain its full essence, so God contains perfectly the divine essence. Whether the expression of 6 is  $2+4$ ,  $3\times 2$ ,  $36-32+2$ , or any of the other infinite means of expressing it, each is a more or less clear expression of the same thing. Similarly, each substance—whether a human, roach, or chimpanzee—is a more or less clear expression of the divine essence. Leibniz concludes: “So do things differ from each other and from God” (A VI iii 519: Pk 77).

The arithmetical analogy makes it easier to see how expression works. Each substance expresses God insofar

as it expresses the divine essence; each expresses the world insofar as the world just is the totality of expressions of God; and finally, each substance expresses every other insofar as each is a more or less clear expression of the same thing. The *Discourse on Metaphysics* employs expression to great effect: “Every substance is like a complete world and like a mirror of God or of the whole universe, which each one expresses in its own way, somewhat as the same city is variously represented depending upon the different positions from which it is viewed” (§9). He goes on to add that substances are “different expressions of the same universal cause, namely, God,” where “the expressions vary in perfection” (§15).

Nor should we worry that creatures have become “little Gods.” Although in the *Monadology* Leibniz is happy to describe human minds as “images of the divinity itself” (§83), he always distinguishes between the perfection of God and the limitations of creatures. In the *Monadology*, he insists that “what is limited in us is limitless” in God (§30), and argues: “God alone is the primitive unity or the first simple substance; all created or derivative monads are products, and are generated, so to speak, by continual fulgurations of the divinity from moment to moment, limited by the receptivity of the creature, to which it is essential to be limited” (§47).

## GOD, MIND, AND KNOWLEDGE

The Platonism of Leibniz’s professors bequeathed to him central concerns relating to mind. In the *Phaedo* Plato argues that it is “the divine-like” nature of the soul that guarantees its self-sufficiency, vitality, and unity. Because the soul remains “always the same as itself,” it is immortal. The body, because it is never the “same as itself,” is mortal (80a–e). Subsequent Platonists had to explain how the soul and the body could be causally related. Among the explanatory alternatives, the fifteenth-century Platonist Marsilio Ficino offered a version of one that influenced Leibniz strongly. In his *Platonic Theology*, Ficino uses the causal theory of emanation to bind the body to the soul. According to Ficino, the soul, which is “always alive,” emanates its “vivifying” and “indivisible power” to its body so that it “causes life to be diffused” and thereby creates a harmony of components. As the unifying power of God is to the world, so is the soul to the body (Book II, chapter 3).

Besides a Platonist account of the soul and its relation to the body, the young Leibniz also took up a Platonist epistemology according to which the only true objects of knowledge (as opposed to opinion) are the eternal and immutable Ideas. Many Platonists placed the

Ideas within the soul, where they remain, waiting to become objects of conscious thought. Although Platonists differed about the precise role played by the senses in the acquisition of knowledge, most agreed that the process of coming to know the Ideas was one of removing oneself from the mutable world of the senses and letting one's understanding (*intellectus*) grasp the immutable Ideas within. For some Platonists cosmic sympathy aids in this pursuit of knowledge; the same Ideas that are implanted in souls are also evident in the harmony among creatures in the world. Theists often reinterpreted Plato's realm of Ideas as the mind of God and the Ideas as paradigms employed by God in creation. Acquisition of knowledge of these Ideas is a necessary step toward knowledge of God, to be achieved both by turning away from the world to the immutable ideas within and by attending to the connections among all things.

In some notes written during his stay in Venice in 1690, Leibniz summarizes this Platonist stance: "Each thing is so connected to the whole universe, and one mode of each thing contains such order and consideration with respect to the individual modes of other things, that in any given thing, indeed in each and every mode of any given thing, God clearly and distinctly sees the universe as implied and inscribed." Due to this connection among things:

"when I perceive one thing or one mode of a thing, I always perceive the whole universe confusedly; and the more perfectly I perceive one thing, the better I come to know many properties of other things from it. And from this perfect consonance of things there also arises the greatest harmony and beauty of the universe, which exhibits to us the power and wisdom of the Highest Maker." (AG 103)

**MIND AND ACTIVITY.** From the beginning of his philosophical career, Leibniz associates activity with mind. Whether he calls these principles of activity souls, minds, substantial forms, or monads, the idea is always that the only sources of activity in the world are divine-like principles that have the power to generate unity, self-sufficiency, and vitality. In a note of 1671, he argues: "Just as God thinks things ... because they follow from his nature, so does Mind. ... Mind and God do not differ except that one is finite and the other infinite" (A VI ii 287–288). In the *Monadology*, he notes: "that souls, in general, are living mirrors or images of the universe of creatures, but that minds are also images of the divinity itself, or of the author of nature, capable of knowing the system of the

universe ... each mind being like a little divinity in its own realm" (§83).

For a short period in 1670–1671, Leibniz distinguished between the momentary minds in nature and conscious minds. His published treatises the *New Physical Hypothesis* and *Theory of Abstract Motion* of 1671 employ momentary minds as the cause of the motion in bodies to great effect. By 1676 his commitment to the plenitude has led him to make all minds eternal: "Every mind is of endless duration" and "is indissolubly implanted in matter. ... There are innumerable minds everywhere" which "do not perish" (A VI iii 476–477: Pk 31). In *On the Greatest of Things* minds act constantly and constitute self-sufficient beings that are eternal and indestructible by anything but God. Human minds are created by God and then exist eternally. Nonhuman minds exist from the beginning of the world to its end. Despite appearances to the contrary, Fido the dog does not die but shrinks down to an *invisible core* of substance from which it activates another substance, and so on for all of eternity. This remained Leibniz's view: "There is never total generation nor, strictly speaking, perfect death, death consisting in the separation of the soul. And what we call *generations* are developments and growths, as what we call *deaths* are enfoldings and diminutions" (*Monadology* §73).

**MARKS AND TRACES.** The eternity of all mind-like active things is not an obviously plausible theory. Leibniz endorsed it because the eternity of minds adds significantly to the plenitude and harmony of the world. While developing his opinions about plenitude in *On the Greatest of Things*, he hit upon the idea that each mind-like creature eternally perceives the entirety of the world. Each mind "senses all the endeavors" of all the other minds in the whole history of the world; "no endeavor in the universe is lost; they are stored up in the mind, not destroyed" (A VI iii 393: Pk 47). He came to believe that plenitude requires that each moment in the eternity of the world contain its whole history: past, present, and future. Minds not only sense all the present activities of all the minds in the world, they also retain a memory or *trace* of them: "It is not credible that the effect of all perceptions should vanish" (A VI iii 510: Pk 61). Each mind "retains the effect of what precedes it" and also "has a quality of such a kind as to bring this [state or effect] about" (A VI iii 491: Pk 51).

Thus, in 1676 Leibniz develops a version of his doctrine of marks and traces according to which each mind at every moment includes an effect or trace of all it has done as well as a quality or mark of all it will do. In §8 of

the *Discourse*, he offers the soul of Alexander as an example: “There are vestiges of everything that has happened to him and marks of everything that will happen to him and even traces of everything that happens in the universe, even though God alone would recognize them all” (A VI iv [B] 1534: AG 41). By making minds eternal, allowing them to sense all endeavors, and assigning them traces of all that has gone before and marks of all that will occur, he makes each mind a mirror of the entire course of the world at every moment in time. Each mind reflects or mirrors the entire world at every moment of the mind’s eternal existence. In *Discourse* §15, he summarizes the point in terms of expression: Each substance is of “infinite extension insofar as it expresses everything” (A VI iv [B] 1646). By such means he agrees with Plato “who taught that our soul expresses God, the universe, and all essences” (*Discourse*, §27).

**GOD AND KNOWLEDGE.** Throughout his life Leibniz was keen to acquire information about the world and to contribute to the sciences of his time. He studied history, designed machines, proposed lighting systems, created insurance programs, and contributed to the development of modern physics. Underlying all these enterprises, however, was his commitment to a Platonist epistemology according to which the divine Ideas are instantiated in the creatures in the world and exist in human minds innately. He summarizes this view in §28 of the *Discourse*: “The essence of our soul is a certain expression, imitation or image of the divine essence ... and of all the ideas comprised in it.”

From the very beginning of Leibniz’s philosophical reflections on universal harmony, he recognizes its epistemological significance. In *Elements of Natural Law* (1668–1671), he presents for the first time the main steps that must be taken to acquire knowledge of fundamental truths. Since the goal of human life is to recognize the beauty and harmony in things, and harmony consists in *consonance* beneath apparent *dissonance*, we must learn to see beyond the dissonance. Once we abstract from the confusion of things and begin to recognize the underlying order of the world, the journey to this ultimate knowledge has begun. The first objects of knowledge are our innate Ideas, each of which is also an Idea in God’s mind and so also instantiated in the world. By grasping one of these Ideas in the right way, we begin the process of knowing God and the ultimate nature of things. The goal of life is to recognize that everything is an emanation of God and hence a proper object of love. In a 1671 letter to Arnauld, he concludes this part of the project: “I show

that it is the same thing to love others and to love God, the seat of universal harmony” (A II i 173–174: L 150).

In the *Philosopher’s Confession* (1672–1673), Leibniz clarifies and expands upon the relation between universal harmony and knowledge: “The nature of mind is to think; therefore, the harmony of the mind will consist in thinking about harmony; and the greatest harmony of the mind or happiness will consist in the concentration of universal harmony, i.e., of God, in the mind” (A VI iii 116–117). The goal of life is to intuit the essence of God, which is evident in the “universal harmony” of the world. The means to this goal is to grasp “the eternal and immutable ... Ideas” (A VI iii 120). The journey to knowledge begins when one “withdraws from the senses and draws back into his own mind.” After a sincere “struggle toward the truth,” “a stroke of light” may appear “as a split in the darkness” (A VI iii 120–121). Through the proper approach to the world, it is possible to be “admitted to God, i.e., universal harmony,” to grasp it “in a single stroke of vision,” and thereby to have “delight without end” (A VI iii 139). However, because minds are mostly “deformed” and exist “in shadow,” many fail to recognize the “wondrous” interconnections among things (A VI i 464–465).

Leibniz remained committed to this form of innatism throughout his life. Thirty years after the *Elements of Natural Law*, he criticized the empiricism of Locke’s *Essay concerning Human Understanding* in his own *New Essays*, noting that innate ideas distinguish us from beasts. According to Leibniz: “This is how ideas and truths are innate in us, as natural inclinations, dispositions, habits, or potentialities.” Agreeing with Plato, he maintains: “The soul contains from the beginning the source of several notions and doctrines, which external objects awaken on certain occasions.” Endorsing Paul’s approach to knowledge, he quotes Paul’s Letter to the Romans (2:15): “The law of God is written in our hearts” (A VI vi 49–52: AG 292–294).

Universal harmony increases the possibility for knowledge; the mirroring of minds increases it still more. For Leibniz *the wisdom of God* requires that creatures mirror one another and thereby add to the beauty and harmony of the world. He was motivated to convert the world into a harmony of mirroring substances at least partly in order to maximize the likelihood of such reflective awareness. The mirroring of minds increases variety and harmony because each mind encompasses the whole of existence. In *On the Greatest of Things*, each mind perceives the entire world at every moment of its eternal existence: “It seems to me that every mind is omniscient

in a confused way, that any mind perceives simultaneously whatever happens in the entire world” (A VI iii 524: Pk 85). In developing these views about plenitude and harmony, he reasons that it is good to maximize the number of diverse creatures in the world; it is even better to maximize the perception of that infinity of good things by making each creature mirror every other; but it is best to maximize the harmony among creatures by making all minds connected to all others at all moments in the eternity of the world.

Leibniz is rarely as explicit about the close relation between emanation and knowledge as he is in *On the True Mystical Theology*, a German text written (probably) in the final years of the seventeenth century. He begins with the metaphysics of universal harmony and its related epistemology: “Every perfection flows immediately from God. Only the inner light that God himself kindles in us has the power to give us a right knowledge of God.” But it is not easy to acquire this knowledge: “The divine perfections are concealed in all things, but very few know how to discover them there. Hence there are many who are learned without being illumined, because they believe not God or the light but only their earthly teachers or their external senses and so remain in the contemplation of imperfections.” Each created thing or “self-being” is from God and is therefore “a single self-sufficient” and “indestructible thing.”

This separateness from God makes it difficult to recognize the divinity within us, but in our connectedness to God, it becomes easy: “God is the easiest and the hardest being to know.” We can find “the essential truth” by seeking out the attributes of God: “The knowledge of God is the beginning of wisdom, the divine attributes are the primary truths for the right order of knowledge.” Once we acquire knowledge of an attribute of God, which is present within us as an innate idea, we begin to approach “the essential light,” which is “the eternal Word of God, in which is all wisdom, all light, indeed the original of all beings and the origin of truths. Without the radiation of this light no one achieves true faith, and without true faith no one attains blessedness.” He summarizes: In each mind “there lies an infinity, a footprint or reflection of the omniscience and omnipresence of God.” Were we to acquire this “right knowledge of God,” we would thereby attain “all wisdom, all light, indeed the original of all beings and the origin of all truth” (Guhrauer, 411–412: L 367–369).

## LOGIC, TRUTH, AND PEACE

Biographers have claimed that as a boy Leibniz became dissatisfied with the categories of Aristotelian logic. Whatever truth there is in this, the youthful Leibniz joined the growing debate about the possibility of a universal language and a formal system for determining truth. For many seventeenth-century philosophers, the hope was to construct “an alphabet of human thought” that would form the basis for a universal language and a means of identifying truths. Leibniz intended to find a way to assign letters or numbers to the elements of thought so as to produce, “through the analysis of words” a means of judging the truth of all statements in the language. In *Dissertation On the Combinatorial Art* (1666), a young Leibniz begins work on this project, which he calls “the universal characteristic.”

Although scholars have often treated Leibniz’s account of logic and truth independently of his views about God and emanation, the two parts of his philosophy are closely related. The divine Ideas are the source of all truths, and human minds contain these Ideas innately, so the analysis of truth will involve these Ideas. Opening one of the main sections of *Dissertation On the Combinatorial Art*, he explains: “To begin at the top, Metaphysics treats being and the affections of being” (VI i 170: L 76). In 1671 he observes that although we are “conquerors of the world,” we cannot have real knowledge until the mind has clarity about itself (A VI i 459). Leibniz’s account of emanation and divine Ideas constitute a major part of the foundation for his program in logic because the ideas innate in us are also those emanated by God in the creations of the world. This connection persists in his thought until the very end; in the *Monadology* he observes that our mind contains “knowledge of eternal and necessary truths ... thus in thinking of ourselves we think of being” and “of the immaterial and of God himself” (§29–30).

The relation between being and truth motivates other projects related to language. As with many of his contemporaries, Leibniz was fascinated with the evolution of languages since the “original language” of Eden. Many assumed that the language spoken by Adam and Eve made the truth more perspicuous and so attempted to recreate it. He went beyond most of his contemporaries in his fascination with the Chinese—both their language and culture. Like many of the Jesuit missionaries in China, he believed that the (apparently) extraordinary insights of the Chinese proved that the *elements of truth* were available to any who knew how to seek them and

that the identification of such truths would promote universal communication and eventually universal peace.

### GOD, EVIL, AND THE BEST

**PHILOSOPHER'S CONFESSION.** Written within a year of his arrival in Paris, the *Philosopher's Confession* is a dialogue in which Leibniz discusses at length and for the first time the problem of evil, a problem that, together with a group of related problems, would engage his attention for the next forty years. The problem is ancient: How can the evil in the world (say, the suffering of innocents) be reconciled with the existence of an infinitely powerful, just, and good Supreme Being? Already in 1672–1673, he has a solution, one that would remain an important part of his thinking: The goodness of God is sufficient reason to create a world that is the best possible, and (apparent) evil is a necessary part of such a world. His solution is embedded in his notion of universal harmony: The world is the best and most harmonious possible despite the fact that its enormous diversity includes events that often suggest otherwise.

In order to explain how this world is best, it was necessary to develop a more thorough-going account of creation. Leibniz did this in the *Philosopher's Confession*. The divine intellect contains an unspecified number of eternal and immutable Ideas that constitute the divine essence and that God wills to instantiate in the world. That is, the essence of God “contains” the “nature of the things themselves” (A VI iii 124). But the essence of God does not necessitate *this* nature of things. Rather, God selects among possible versions of the divine essence and then emanates the selected version so as to create and sustain the world. He refers to these versions as possible *series of things*; he will later call these possible worlds. Each individual created thing is an instantiation of the (selected) divine essence. Further, God has a sufficient reason for choosing each thing, and each thing has a sufficient reason for acting as it does. He summarizes his position: “The present state of things depends on the series of things. The series of things depends on the universal harmony. The universal harmony depends on those well-known eternal and immutable ideas themselves ... contained in the divine intellect” (A VI iii 131). God is “the sufficient and complete reason” for the world (A VI iii 123). God understands this world to be most harmonious and thereby has sufficient reason to choose it.

Leibniz's *best possible world* solution to the problem of evil gives rise to further problems: One concerns (what scholars sometimes call) the *author of sin*; another concerns the status of human freedom. On Leibniz's account,

God causes evil, for God creates the best series of things, including many things that are, when considered in themselves, bad or sinful. In the *Philosopher's Confession* he responds to this problem by pointing out that God takes no delight in the existence of evil and hence is not properly thought to will it. In later works, he came to regard this response as inadequate. According to Leibniz, there is a sufficient reason for every thing that happens in the world. As we will see below, this principle plays an important role in his thinking about the world. When applied to the problem of human freedom, the principle commits him to determinism. For Leibniz, the will is never free of antecedent causes and in that sense it is always determined. But he is also a compatibilist in the sense that, just as God's perfect freedom does not involve lack of determination by the divine essence, so human freedom does not require undetermined choices. Freedom requires only spontaneity, or more exactly, the sort of spontaneity possessed by rational substances.

In both the *Elements of Natural Law* and *Philosopher's Confession*, Leibniz's approach to the problem of evil also has an epistemological aspect. The nature of universal harmony makes the acquisition of knowledge both more difficult and more *glorious*. Because there is a struggle, there will be some who fail. Yet the world is a better place because of the struggle to recognize the harmony among all things. When one sees an “unexpected” unity “where no one would suspect a connection” (A VI i 484–485), there is more delight and happiness. “The most confused discord fits into the order of the most exquisite harmony unexpectedly, as a painting is set off by shadow, as the harmony due to dissonances transforms the dissonances into consonance” (A VI iii 126). “Given that the whole is pleasing, it does not follow that each part is pleasing. ... Only the whole is pleasing, only the whole is harmonious” (A VI iii 130). For Leibniz the beauty and goodness of the whole justifies the *apparent* ugliness and evil of some parts. In the end, the world is better because apparent disorder will “unexpectedly” reveal “the wonderful reason” behind this “greatest” of symmetries (A VI iii 122).

**THEODICY.** Leibniz's last extended treatment of the problem of evil restates many of the themes from the *Philosopher's Confession*, written almost forty years earlier. The *Theodicy* is a long, digressive work, devoted mainly to the topics listed in its subtitle: the goodness of God, human freedom, and the origin of evil. But the book also functions as a defense of the consistency of faith and reason. It is divided, rather arbitrarily, into three *essays*, preceded by an author's preface and a “Preliminary Dis-

sertation on the Conformity of Faith with Reason,” and succeeded by various appendices.

Much of the *Theodicy* consists of Leibniz’s responses to other authors, Bayle in particular. His own metaphysical system is in the background. His idealism, for example, is barely mentioned at all. But the characteristic themes of his philosophical theology nevertheless dominate the text, and it is in the *Theodicy* that his most complete response to the problem of evil is found. That response is, at its core, the same as the response that he gave in the *Philosopher’s Confession*: that this is the best, that is, the most harmonious of all possible worlds; that the evils within it are not to be judged apart from the entire series of things; that God’s perfection requires that only the best possible world be created; that humans therefore cannot reasonably wish that things had been different; that happiness is to be sought through understanding the perfection of God, the creator of all things, and the perfection of all the things that God has created.

The problem of the author of sin, to which Leibniz had given only a weak response in the *Philosopher’s Confession*, is in the *Theodicy* handled with much more verve and power. He distinguishes between God’s antecedent and consequent will. God wills each possible thing antecedently in proportion to its perfection. But some possible things are not compossible with others, so not all God’s antecedent willings can be realized. God’s consequent, that is, final and decisive, will is the existence of that series of things that realizes as much perfection as possible. To this account is added an Augustinian idea of metaphysical evil as mere privation or limitation. Thus, God does not will evil at all, for God’s willing is directed only toward the perfection in things, and imperfections are nothing at all, and so not even possible objects of will.

The *Theodicy* contains extensive discussion of freedom, including many objections to so-called *freedom of indifference*—the capacity to choose between alternatives that are equally advantageous (or disadvantageous). Leibniz’s commitment to the principle of sufficient reason rules out any such capacity, even in the case of God—a conclusion that plays a significant role in some of the argument in his later correspondence with Clarke. He allies himself with Augustine and the Thomists in holding that everything is determined and with Aristotle in requiring as conditions of freedom only spontaneity and intelligence. The rejection of a contraccusal account of freedom also reflects Lutheran doctrine, and one of the declared goals of the *Theodicy* is to provide an account of human freedom on which Catholics and Protestants can agree.

As in other writings Leibniz struggles in the *Theodicy* to give an account of contingency that avoids necessitarianism. Absolute or metaphysically necessary truths exclude any alternative; they rely on the principle of non-contradiction. This kind of necessity is incompatible with freedom, and not even God is free with respect to these truths. Thus, according to Leibniz, God was not free to create spaces with fewer or more dimensions than three, for such spaces are logically impossible. Physical and moral necessity, by contrast, resting on the principle of sufficient reason, is not incompatible with freedom. God is free in choosing to create the best possible world because there are other worlds that are possible in themselves (even though God, being perfect, would not in fact create them); rational creatures are free in the choices they make if there are other options (even though, given preceding causes, they will not in fact choose them). His compatibilist account of freedom appears here in its starkest form: Both divine and human freedom require only the bare logical possibility of some alternative course of action. God is perfectly free because perfectly rational; humans are imperfectly free because less than perfectly rational. Acting against or without reason is, for Leibniz, the paradigm case of unfreedom.

This compatibilism, even if acceptable, leaves little room for contingency, and scholars have long argued the question whether Leibniz manages to avoid the claim that everything that happens, happens necessarily. His standard answer, given many times in the *Theodicy*, is that it depends what sort of necessity is intended. Nothing happens by logical necessity except when the opposite involves a contradiction; everything happens by moral necessity, for unless this entire *series of things* were the uniquely best, God would lack a sufficient reason to create it. It is nevertheless hard to see how any other series of things is ever possible given the necessary existence and perfection of God. Here the tension between his Platonism and the voluntarism of the Christian tradition is at its greatest.

Leibniz himself seems never to have wavered from the underlying optimism of his account of *the best of all possible worlds*. He often notes that he knows no one as happy as he. He summarizes the source of his contentment in a letter to Queen Sophie Charlotte:

But the consideration of the perfection of things, or, what is the same, of the supreme power, wisdom, and goodness of God, who does everything for the best, that is, with the greatest order, is sufficient to make all reasonable people content, and to convince them that contentment

should be greater to the extent that we are disposed to follow order or reason.” (AG 192)

Leibniz’s optimism, and his claim that this is the best of all possible worlds, was viciously satirized by Voltaire in *Candide*. But Voltaire’s Dr. Pangloss, the representative of optimism, is a very unreliable guide to Leibniz, or even to the Leibnizianism of his disciple Wolff. Leibniz, from the *Philosopher’s Confession* on, insists that the best possible world is not best in all of its parts. By the time of the *Theodicy*, he has a battery of arguments against the kinds of objections that Voltaire advances. But Voltaire’s short and witty tale is a far better read than the long and, at times, tedious *Theodicy*, so it is not surprising that its *argument* is better liked.

### SUBSTANCE, MATTER, AND NATURE

At the very end of his life, Leibniz explains that in order to understand the intellectual *discoveries* of others, it is often necessary “to detect the source of their invention” (G III 568). In presenting his views about God, creation, mind, activity, knowledge, and harmony, it is helpful to detect their Platonist sources. In order to understand his *discoveries* about the natural world, it will be necessary to detect the sources of his *invention*.

**ARISTOTELIANISM AND MECHANISM.** For most of his life Leibniz takes there to be two kinds of basic, natural entities, or substances. The first sort is a corporeal substance constituted of two *principles of nature*: one active, one passive. Corporeal substances are analogous to organisms: They are active, unified things with a material component or body and an organizing principle. The second kind of substance is variously called “mind, soul, spiritual substance,” and “substantial form[s].” Although these are the active things in nature, which are tied to a material component of some sort, they are themselves also substances. Toward the end of his life, Leibniz began to call the ultimate components of nature monads. In the world of his monadology, there are only mind-like simple substances in various collections.

The Aristotelian philosophy offered the raw materials for Leibniz’s account of substance; the new mechanical philosophy constituted the basis for his physics. Although he transformed those philosophies to suit his own philosophical and theological needs, he remained wedded to (what he considered to be) Aristotle’s basic insights about the self-sufficiency of substances and to the mechanists’ commitment to explain corporeal phenomena in terms of matter and motion.

For most Aristotelian philosophers, natural objects are constituted of two principles, matter and form, and natural events are explained in terms of the actualization of the potency of these two principles. When Leibniz began constructing his own philosophy in the mid-1660s, there was a new explanatory model available, one that had greatly diminished the power of the scholastic model. According to the mechanical philosophy (as it came to be called), nature is composed of matter—whether the extended stuff (*res extensa*) of Descartes, the atoms of Gassendi, or one of the many less popular accounts of corporeity—whose actions and movements cause and explain all the phenomena of nature. For the mechanist all physical phenomena are to be explained in terms of some kind of matter and motion. Although these thinkers disagreed about how to define the material component in nature, they all took it to be void of substantial forms.

Despite the genuine innovation of the new mechanical philosophy, it failed to solve adequately a number of important theological and metaphysical problems. By the middle of the seventeenth century, especially in the Protestant areas of northern Europe, a number of conciliators took it upon themselves to *reform* the Aristotelian philosophy rather than abandon it. Different reformers had different recipes for mixing the old with the new, but they all combined some part of the mechanical physics with Aristotelian metaphysics. Each claimed that, when properly understood, the Aristotelian philosophy could comfortably accommodate mechanical philosophy. Like these reformers, Leibniz also recognized very early on that the Aristotelian theory of substance could easily accommodate the new mechanical physics and thereby explain the phenomena.

The Aristotelian philosophy appealed to the young Leibniz for several reasons. At the heart of the Platonized Aristotelianism that his mentor, Jakob Thomasius, bequeathed to him stands the idea that nature is constituted of individual corporeal substances whose substantial forms act to compose a divinely arranged harmony. From the beginning of his philosophical career, Leibniz embraced the assumption that everything in the world acts to instantiate the good. Unlike those of his contemporaries who rejected final causation, he embraced the Aristotelian idea that nature moves toward the good. For Leibniz, an Aristotelian account of substance formed a secure foundation for such a rational, harmonious, and good world although it needed to be *reformed* to fit mechanical explanations in physics. He committed himself to the Aristotelian and mechanical philosophies as a youth and maintained this commitment until his death.

In the *Monadology* he writes: “Souls act according to the laws of final causes. . . . Bodies act according to the laws of efficient causes or of motions. And these two kingdoms, that of efficient causes and that of final causes, are in harmony with each other” (§79).

Leibniz had excellent metaphysical reasons to accept a major part of the Aristotelian philosophy. But he had other incentives as well. From the perspective of war-ravaged Germany, Aristotelianism must have seemed to Leibniz the safest bet as a philosophy of religious reconciliation. The doctrinal declarations of contemporary Catholics were framed in Aristotelian terms while Aristotelianism survived in Lutheran cities such as Leipzig. Aristotelian notions of substance thus presented themselves as ideal both for understanding the divinely arranged harmony in the world and for working toward religious and political harmony within it.

**SUBSTANCE, SELF-SUFFICIENCY, AND THE REFORMATION OF THE MECHANICAL PHILOSOPHY.** The young Leibniz intended to transform the Aristotelian notion of substance so that it would accommodate mechanical physics. For Leibniz, the mechanical physics of philosophers such as Descartes, Hobbes, Gassendi, and Galileo reduces to the following claims: There is some sort of matter or extended stuff (*res extensa*), which is (somehow) moved and whose arrangements both cause and explain the corporeal features of individual bodies; therefore, a body is organized *res extensa*, and all corporeal features are reducible to the arrangements of such extended stuff. Leibniz was *never* satisfied with the metaphysical foundations offered by leading proponents of the mechanical physics; the physical explanations of particular phenomena seemed adequate, but the metaphysical underpinnings of those explanations did not.

Leibniz’s most fundamental assumption about the natural world is that it is composed of substances, each of which has its own source of activity by means of which it is constituted as a self-sufficient, unified thing. The material stuff of the mechanical philosophers did not have its own internal source of activity and so was neither self-sufficient nor properly unified; it therefore could not by itself constitute genuine substances. In his earliest comments about substances, Leibniz explains that because the corporeal substance of the mechanists “is not self-sufficient . . . an incorporeal principle must be added” (A VI i 490: L 110). This incorporeal principle is a substantial form or mind that organizes the matter and thereby makes it into a unified, self-sufficient thing. He corrects the mistakes of the mechanists by making substance

active, allowing it to be both causally and explanatorily complete. He demotes the matter of mechanical physics to the status of the passive principle in substance and insists that the active mind or substantial form organizes the passive principle so as to make a unity with it.

The result is an individual corporeal substance that can act as the cause and explanation of its own (at least) basic features. Although the details of his views about substance will continue to evolve over the course of his long philosophical career (e.g., he comes to conceive the passive principle as itself constituted of mind-like substances and eventually prefers to construct the world entirely out of monads), he never wavers from his commitment to the causal and explanatory autonomy of the fundamental entities of nature. It is this robust self-sufficiency that is his most profound debt to the metaphysics of Aristotle. And it is this robust self-sufficiency that inspired many of the core doctrines of his mature thought.

## THE METAPHYSICS OF SUBSTANCE BEFORE 1680

For much of the twentieth century, scholars maintained that Leibniz developed his theory of substance in the 1680s. Except for a few scattered works—mostly those in logic and physics—his earlier texts were either neglected or dismissed as juvenilia. However, close attention to writings from the 1660s and 1670s reveals that Leibniz developed his theory of substance much earlier. In this section we consider the most important of the early texts.

**ORIGINAL ASSUMPTIONS ABOUT SUBSTANCE, ACTIVITY, AND SELF-SUFFICIENCY.** During the mid-1660s, Leibniz worked on a number of related projects in law, logic, and theology. Encouraged by the distinguished German statesmen Boineburg, he began composition of the *Catholic Demonstrations* in 1668. The work, as Leibniz conceived it then, was to consist of a series of philosophical prolegomena and four parts. The prolegomena were to contain the *elements of philosophy*, that is, the *first principles* of metaphysics, logic, mathematics, physics, and practical philosophy, while the four parts were to be demonstrations of the existence of God, the immortality of the soul, the Christian mysteries (e.g., the Eucharist), and the authority of the church and scripture. The work was designed to offer a metaphysics that would cohere with Catholic and Lutheran doctrine and thereby effect a reconciliation between the two churches. But another sort of reconciliation is promoted within the work, for when Leibniz began the *Catholic Demonstrations*, he was

committed to a version of Aristotelian philosophy as he interpreted it and also to a mechanical account of the phenomena of nature.

The theological writings indicate exactly how his reconciliation of these two philosophies evolved in his attempt to explain the theological doctrines of the Eucharist, the immortality of the soul, and so on. He takes the Aristotelian notion of substantial form as the active principle of nature and combines it with the mechanical notion of passive extended stuff as the passive principle to create a coherent *reformed* Aristotelianism. At work in these theological essays are a number of philosophical assumptions. The most important of these are as follows (except for the Principle of Sufficient Reason, the names are not his):

- The *principle of substantial activity* assumes that a being is a substance if and only if it subsists per se, and a being subsists per se if and only if it has a principle of activity within its own nature.
- The *principle of sufficient reason* assumes that there is a complete or sufficient reason for everything.
- A *complete reason* for a state or feature *f*: (1) constitutes the necessary and sufficient condition for *f*; (2) is perspicuous in that, in those cases where one can understand it, one sees exactly why *f* as opposed to some other state of affairs came about; (3) is such that in those cases when a full account of it can be given, that account constitutes a complete explanation of *f*; and (4) does not require a reason of the same type.
- The *logical assumption* claims that, for any state or feature *f*, the logically necessary and sufficient conditions of *f* exist and in theory can be articulated.
- The *intelligibility assumption* claims that those conditions are in theory intelligible.
- The *substantial nature assumption* claims that every substance has a nature that contains the set of necessary and sufficient conditions or the complete reason for those features that strictly belong to it, and moreover, those conditions are in theory intelligible.

The precise status of these assumptions in the *Catholic Demonstrations* and related early texts is unclear. They constitute the underlying principles of Leibniz's discussions during this period. Although in the texts of 1668–1671 they may have the status of working hypotheses, they continue to inform and direct his thinking about metaphysical matters for years to come. Some of his most

characteristic doctrines directly develop from these assumptions.

**SUBSTANTIAL FORMS AND ACTIVITY.** While developing his account of substances as the fundamental entities of nature in 1668–1671, Leibniz was also working on the *Elements of Natural Law*. As his views about universal harmony evolved, he integrated his Platonist assumptions about activity, emanation, and unity into the Aristotelian and mechanical assumptions about self-sufficiency, substantial forms, and matter. He assumes that substantial forms are divine-like and possess the kind of metaphysical powers described by Ficino. The idea here is that God continually emanates the divine essence to each individual mind and furnishes each mind with its own source of activity thereby generating unity and self-sufficiency. He suggests that each active thing acts constantly according to a *reason* given it by God: “Just as God thinks things ... because they follow from his nature, so does Mind” (A VI ii 287–288). By being Godlike the active principles or substantial forms possess divine-like features, such as unity and self-sufficiency. They also act according to a divinely arranged *reason* (A VI i 534).

The principle of substantial activity reveals the close relation between substancehood and activity: Anything that possesses its own source of activity will be self-sufficient and hence substantial. In Paris, Leibniz develops this idea so that mind-like, active things are indestructible and the source of the individuality, unity, and identity of the corporeal substances of the world. No active creature is ever without a body or passive principle; only divine mind is “devoid of body” (A VI iii 100). God “arranged all things from the beginning” (A VI iii 477: Pk 31) so as to give each created substance a *rule* or set of instructions by means of which it acts (VI iii 483: Pk 39). As he summarizes his position:

There are certainly many and important things to be said ... about the principle of activity or what the scholastics called substantial form, from which a great light is thrown on Natural Theology and ... the mysteries of faith. The result is that not only souls but all substances can be said to exist in a place only through the operation of their active principle, that souls can be destroyed by no power of body; and that every power of acting exists from the highest mind whose will is the final reason for all things, the cause being universal harmony; that God as creator can unite the body to the soul, and that in fact, every finite soul is embodied, even the angels are not excepted. (A VI iii 158)

In the pre-Paris period, minds are considered constantly active and therefore self-sufficient, unified things. In *On the Greatest of Things*, written during his final year in Paris, Leibniz develops and expands on the relations between activity, self-sufficiency, unity, and divisibility: “whatever acts cannot be destroyed” naturally, and yet “whatever is divided is destroyed” (A VI iii 392–393: Pk 45–47). Mind or substantial form acts as the “cement” in a corporeal substance and thereby guarantees that its passive principle will not be divided (A VI iii 474: Pk 27). Consistent with the theory of corporeal substance developed earlier, the mind-like substantial form acts constantly through its passive principle to create a single “unsplittable” thing, which Leibniz sometimes calls an “atom” (A VI iii 393: Pk 47). This atom or unified thing is a corporeal substance constituted of an active and a passive principle. Consistent with the substantial nature assumption, the nature of the substance acts as the necessary and sufficient condition of its features. In 1676, then, the activity of mind individuates the substance, unifies it, and makes it eternal. Throughout a substance’s eternal existence, it is its active principle that will organize its passive principle so as to constitute its eternally self-sufficient nature.

In these early years the persistence of the substantial nature through various changes is especially important to Leibniz because of his concern for developing a metaphysics consistent with Christian doctrine. The doctrine of resurrection, for example, gives rise to the question: How can it be the same human substance that persists through the radical changes in a human life, then dies, and then is resurrected? He explains that the mind “is firmly planted in a flower of substance [that] subsists perpetually in all changes” and that can be “diffused” through a greater or less expanse of the original body (A VI iii 478–479: Pk 33). The mind-like principle of activity acts as the *cement* of the substance and forms the unity that persists through all substantial changes, including even bodily death and resurrection. In a letter to Johann Friedrich of 1671, he explains that in the same way that “God is diffused through everything,” so mind is diffused through its body; just as the activities of God do not diminish the divine essence, so too the mind acts on its body “without being diminished” (II i 113).

It is clear from these texts of 1670–1676 that Leibniz believes he has hit upon an account of substance that comfortably accommodates the severe metaphysical demands of Christian doctrine, the physical explanations of the mechanists, and the Aristotelian commitment to the causal completeness and self-sufficiency of substance.

Although the details of his position are in flux and will shift over time, the basic structure of this account of substance will not vary until the development of the world of the monadology. For Leibniz, a corporeal substance is a self-sufficient and unified thing that results from a substantial form activating and organizing its passive principle. The substantial form acts constantly on its passive principle by a *set of instructions* given it by God. The passive principle is the substantial form’s *instrument of acting*. The unity is what results from the constant activity of the active principle on the passive one, thereby forming an organized unified thing.

**MATTER, EXTENSION, AND PASSIVITY.** Within weeks of entering the University of Leipzig, at the age of fourteen, Leibniz had a major philosophical insight. He recalls walking in some woods near his home and “deliberating whether I should keep the substantial forms” or convert to mechanism. In the end he decided to accept the physical explanations of the mechanical philosophers as opposed to those of the scholastics and thereby “to apply” himself to mathematics (G III 606: L 655). The young Leibniz thus assumes that the passive principle in corporeal substances is material, like the *res extensa* of Descartes. For the next few years he maintains that the active principle or substantial form takes this passive extended stuff, organizes it into an individual body, and thereby creates a unified thing or corporeal substance.

In the theological essays of 1668–1671, he conceives the union between the active and passive principles as involving constant activity, where the mind-like substantial form cannot “act outside itself” except through its passive principle (A VI i 533–534). The unity here is analogous to that in organisms in the sense that if the activity involved in maintaining an organic unity stops, so does the unity. When the maintenance of the organization ceases (e.g., the heart stops, the liver no longer functions), the unity of the substantial form and matter does so as well (e.g., the entity dies, the formerly organized body becomes a heap of decaying flesh). The nature of organic unities also helps us to understand what he means when he says that the active principle cannot act outside itself except through the passive: In order to act externally, the source or cause of the organization has to act through the passive principle that it organizes.

In the 1670s Leibniz became dissatisfied with this account of passivity. There were several problems. First, the mechanical account of body could not easily accommodate important theological doctrines, such as the Eucharist and resurrection of the body. According to the

Lutheran account of the *mystery* of the Eucharist, the body of Christ and the body of the bread exist side by side. However, if the body of Christ is a collection of extended stuff, it is unclear how it can be distinct from and coextensive with the extended stuff that constitutes the matter of the bread. Leibniz argues: “For if body and space are one and the same, how can we avoid the consequence that in different spaces or places there must be different bodies” (A VI iii 157–158). He concludes that the views of the mechanists, who believe that *the essence of body consists in extension*, are therefore incompatible with the miracle of the Eucharist. He also argues that since, according to Descartes and other mechanists, each body is constituted of extended stuff and since all extended stuff is essentially the same, it becomes enormously difficult to give any particular body (say, Christ’s body) a stable identity. Leibniz concludes: “One cannot say... why it is called the body of Christ rather than bread, to which it is very similar” (A II i 170). Nor, to take the case of another Christian doctrine, can one say how to identify and individuate bodies at the time of the resurrection.

Another problem facing Leibniz’s early account of the passive principle in corporeal substance is less overtly theological. According to the principle of plenitude as he interpreted the ancient doctrine, the world is as full of diverse being as possible. But according to the version of Platonism that Leibniz learned as a university student, matter is uniform, divisible, unreal stuff. In the *Phaedo*, Plato describes it as “as unintelligible, soluble and never consistently the same” (80e). Matter lacks all unity and activity; it contributes nothing positive to the world. It follows from these Platonist assumptions that the world would be made better by filling it with mind-like unified things and stripping it entirely of extended passive matter.

There has been much disagreement among scholars about when Leibniz does finally strip the world of extended stuff. Once we take seriously Leibniz’s interest in Platonism and his concern to solve the theological problems posed by doctrines such as the Eucharist and resurrection of the body, it seems relatively clear that he abandons extended stuff while still in Paris although he remains undecided about what exactly to put in its place. In the Paris texts he asks as many questions as he answers: “Since mind is something that has a certain relation to some portion of matter, it must be stated why it extends itself to this portion and not to all adjacent portions; or why it is that some body, and not every body, belongs to it in the same way” (A VI iii 392: Pk 45). In 1676 he did

not have consistent answers to these questions; the texts are unclear about the precise nature of the passive principle in substances. However, one of the hypotheses that he entertained is that bodies are themselves unextended collections of mind-like substances whose only actions are perceptual states.

**BODY AND FORCE.** The young Leibniz embraced mechanical physics, according to which the features of bodies are to be explained in terms of the broadly geometrical properties of their parts—whether these are tiny indivisible atoms or infinitely divisible stuff—whose configurations shift and change through motion and whose motion changes through collision. When he published his *New Physical Hypothesis* and *Theory of Abstract Motion* in 1671, he agreed with the standard mechanical account of collision as the only means by which bodies naturally change motion. His *abstract* account of motion is offered in terms of the Hobbesian notion of conatus, defined here as “an indivisible, nonextended part of motion” and as “the beginning and end of motion” (A VI ii 264–265: L 139–140). In 1671 he agreed with Descartes that “all power in bodies depends on speed.” If two bodies with unequal speeds collide, they will move together after the collision in the direction of the faster body with a speed that is the difference between the two (A VI ii 228). By the time he met Spinoza in the autumn of 1676, he had begun to question features of this mechanical account, and in particular, the law of the conservation of motion proposed by Descartes.

In the winter of 1677–1678, Leibniz takes some observations made by Huygens about impact and transforms them into a notion central to his thought. He decides that force or power of action must be conserved in collision between bodies rather than mere speed. By January 1678 he has hit upon the proper account of this force:  $mv^2$  (mass times velocity squared). Given the importance of this insight, it is odd that he does not publish any part of his findings until 1686, and even then, in his *Brief Demonstration*, he merely criticizes Descartes’s conservation principle and ONLY hints at his own account. Over the next few years, he will work out the details of his dynamics, especially in response to Newton’s *Principia Mathematica* (1687).

Leibniz’s discovery of  $mv^2$  was enormously important and radically changed his account of the physical world. As he explains in the *Specimen of Dynamics* (1695), he was forced to recognize that in physics, purely geometrical notions were inadequate: “We must add to material mass a certain superior and so to speak formal principle.

Whether we call this principle form or entelechy or force does not matter so long as we remember that it can only be explained through the notion of force” (GM VI 241: AG 124–135). He notes the easy fit between an Aristotelian approach to substance (whose principle of activity is often described as *form or entelechy*) and the new notion of force. Leibniz had hit upon the basic features of his Aristotelian account of substance in the late 1660s. With the development of his dynamics, all he had to do was to redescribe the active principle in nature. The mind-like substantial forms in nature were now responsible for more than just the activity of creatures; they were also responsible for their force.

**THE PRINCIPLE OF SUFFICIENT REASON.** Leibniz is well known for his commitment to the principle of sufficient reason, which he often calls his *great principle*. As early as 1668 he assumes that God always has a reason for *choosing* one state of affairs rather than another and that this reason must be sufficient. In 1671 he calls the principle a *first* truth; and by way of demonstration, he adds: “Everything that is has all its requisites” since a state of affairs will not exist unless all its requisites “are given. ... Consequently, everything that is has a sufficient reason” (A VI ii 483). Later in his career he articulates the principle in various ways, often in terms consistent with his account of truth. In the *Monadology*, for example, he presents it as the principle “by virtue of which we consider that we can find no true or existent fact, no true assertion, without there being a sufficient reason why it is thus and not otherwise, although most of the time these reasons cannot be known to us” (§32).

Leibniz’s early commitment to the principle is matched by his early application of the principle to God as the sufficient reason of the world and to the natures of substances as the sufficient reason for their features. According to the substantial nature assumption, every substance has a nature that contains the set of necessary and sufficient conditions or the complete reason for its features. But a question arises about which features are covered here. If the nature of a substance is so complete as to contain the sufficient reason for all the features of the substance, then the principle of sufficient reason and the substantial nature assumption together bring us to the brink of two of his more startling metaphysical claims. The first is phenomenalism; the second preestablished harmony.

**PREESTABLISHED HARMONY AND PHENOMENALISM.** Although Leibniz does not use the term *preestablished harmony* until the 1690s (in the 1680s he calls it the

theory of *concomitance*), there is significant evidence that he adopted its constitutive tenets in the 1670s and perhaps as early as 1671. The doctrine of preestablished harmony holds that each substance acts out of its own nature (spontaneity), that no substance causally interacts with any other substance (world apartness), and yet that each substance in the world parallels the activities of all the other substances perfectly (parallelism). The theory is closely related to another component of his mature philosophy: phenomenalism. The phenomenalism of the mature Leibniz, what is sometimes called *well-founded phenomenalism*, includes at least the following two claims: Bodies are phenomenal objects and so our perceptions of them arise from our own internal nature; and our perceptions nonetheless correspond to (parallel) the activities of real (unextended and mind-like) substances and in that sense are *well founded*.

The *New System* of 1695 summarizes the doctrines: “We must say that God originally created the soul (and any other real unity) in such a way that everything must arise for it from its own depths, through a perfect *spontaneity* relative to itself, and yet with a perfect *conformity* relative to external things.” Since our perceptions are “internal perceptions in the soul itself” they “must arise because of its own original constitution,” which is “given to the soul from its creation,” and “constitutes its individual character. ... This is what makes every substance represent the whole universe” from its own point of view, and “makes the perceptions or expressions of external things occur in the soul at a given time, in virtue of its own laws, as if in a world apart, and as if there existed only God and itself.” In the perfectly harmonious world chosen by God, “there will be a perfect agreement among all these substances, producing the same effect that would be noticed if they communicated” (G IV 484–85: AG 143–44).

There is much, though scattered, evidence in the texts of the 1670s that Leibniz adopted most of the claims constitutive of phenomenalism and preestablished harmony early on. Neither preestablished harmony nor phenomenalism came to him suddenly. Rather, their core claims emerged gradually out of his attempts to solve the theological and philosophical problems that most concerned him. As he reflected on problems in ethics, law, theology, physics, and metaphysics, he developed his account of universal harmony and substance in an attempt to solve those problems. Preestablished harmony and phenomenalism resulted from the convergence of these solutions. These elaborate metaphysical doctrines were the most elegant way to solve a diverse group of dif-

difficult problems, to capture the rationality and goodness of God, and to reconcile ancient and modern ideas.

Prestablished harmony may be seen to result from the combination of universal harmony, the self-sufficiency of substances, and the mirroring of substances. According to universal harmony, God emanates the divine essence to every creature. The unity of the world is due to the fact that all creatures express the same thing: its multiplicity to the fact that each creature expresses the divine essence in a different way. The substantial nature assumption may be taken to entail that the complete reason for all the features of a substance is contained in its nature, in which case the complete reason for its perceptual states is contained there as well. The conjunction of the substantial nature assumption and universal harmony suggests spontaneity: For each substance, the manner of its expression of the divine essence will be contained *in its nature*. Further, if we assume that the substantial nature of a substance contains the necessary and sufficient conditions for each and every feature of it, then it seems to follow that the cause of every feature of the substance is *contained* in its nature, which is consistent with world apartness and the idea that there is no causal interaction among substances.

Finally, the theory that each substance mirrors all the others resembles the tenet of parallelism. Indeed, the parallelism of well-founded phenomenalism and preestablished harmony seems to be an extension of the Platonist notion of sympathy: Each substance, in its manifestation of the divine essence, is in perfect sympathy—for Leibniz, in perfect coordination—with every other. The doctrine of marks and traces is itself an elaboration of this notion of sympathy; it is also closely related to the idea that each substance is a world apart. Prestablished harmony is fundamentally emanation and sympathy perfectly organized in the self-sufficient substantial natures of the created world.

In the *Discourse* Leibniz implies that preestablished harmony is the blending of just these assumptions, and he acknowledges its close relation to his phenomenalism: “It is very evident that created substances depend upon God” who “produces them continually by emanation.” In order to manifest divine “glory,” God creates various substances to “express the universe.” It follows from this account of God’s relation to the world that “each substance is like a world apart, independent of all other things, except for God” from “whom all individuals emanate continually.” By acting on us, God arranges things so that “all our phenomena, that is, all the things that can ever happen to us, are only consequences of our

being” such that these phenomena are “in conformity with the world which is in us.” It follows that “the perceptions or expressions of all substances mutually correspond” although each expression differs from every other. Finally, “if I were capable of considering distinctly everything that happens or appears to me at this time, I could see in it everything that will ever happen or appear to me” (A VI iv [B] 1549-51: §14).

Whether or not Leibniz commits himself to phenomenalism in the 1670s, he surely toys with the position. During his Paris period he often reduces the existence of bodies to the consistency of perceptions and concludes: “It does not follow that there exists anything but perception, and the cause of this perception and its consistency.” The cause of perception is such that: “a reason can be given for everything and everything can be predicted” (A VI iii 511: Pk 63-65). From the perspective of conscious beings, in order to explain existence, it is unnecessary to resort to outside bodies; rather, we can reduce all existence to the consistency of perceptions, where the latter includes both the consistency of the perceptions within a mind and the coordination among minds: “We sense or perceive that we exist; when we say that bodies exist, we mean that there exist certain consistent perceptions, having a particular constant cause” (A VI iii 512: Pk 67).

In these and related texts of 1676, Leibniz seems to extend the substantial nature assumption to encompass all the features of substances, including their perceptual states. The suggestion is that God gives each substance a set of instructions or *rule* that makes each substantial nature the sufficient cause of all its features, including its perceptions. Thus, consistent with spontaneity and world-apartness, all the features of a substance are caused by its nature and there is no causal interaction among substances. Consistent with parallelism, “existence consists in” the coordinated perceiving of objects so that “several people perceive the same.” It is “not necessary either that we act on them or that they act on us, but only that we perceive with such conformity” (VI iii 511: Pk 63). As a “perfect mind” God “arranged all things from the beginning” so as to make them “most harmonious” (A VI iii 474–476: Pk 25–29). For Leibniz in these texts of 1676, a major theme in this harmony is God’s coordination of the perceptions among minds. Indeed: “Without sentient beings, nothing would exist. Without one primary sentient being, which is the same as the cause of all things, nothing would be perceived” (A VI iii 588: Pk 113). As he writes to Malebranche in 1679, “I have always been con-

vinced ... that strictly speaking bodies do not act on us” (A II i 472-73: L 210).

## THE METAPHYSICS OF SUBSTANCE, SECOND STAGE

Written during a snow storm in the Harz mountains in 1686, the *Discourse on Metaphysics* is the first general account of Leibniz’s mature metaphysics. He sent a synopsis to Arnauld and thereby began the well-known correspondence between these two great seventeenth-century thinkers. Although not published during his lifetime, the *Discourse* and the correspondence with Arnauld, together with the terse summary of metaphysics contained in *First Truths*, have been favorites of twentieth-century Leibniz scholars. These texts have received a large amount scholarly attention, some of which is excellent. But we now know that many of their most important doctrines developed years earlier. For the most part, the *Discourse* and *First Truths* are summaries of doctrines extant in the 1670s, and what is new in them develops neatly from earlier views.

**SUBSTANCES, SUBJECTS, AND TRUTH.** In 1900 Bertrand Russell published a book in which he argued that Leibniz’s metaphysics developed from his logic and theory of truth. For much of the twentieth century, scholars agreed with Russell that the theory of truth offers the key to Leibniz’s philosophy and that the theory of substance developed out of that theory. With access to more of his writings and through attention to the sources of his ideas, it is clear that the core of his metaphysics—the account of substance and the theory of universal harmony—developed several years before the theory of truth. So, though the mature Leibniz sometimes puts the theory of truth front and center, it developed out of his views about the self-sufficiency, intelligibility, and explanatory completeness of substances; it was a consequence of those other views, not their source.

In 1676 Leibniz begins to emphasize subjects as the bearers of features. This is an important clarification of claims contained in the core metaphysics and constitutes a step toward the development of his conception of truth. One of his basic, Aristotelian assumptions is that substances are causally and explanatorily self-sufficient (at least with regard to their primary features). Another is that the relation between a feature and the substance to which it belongs is both logical and intelligible. These logical and intelligibility assumptions imply, for any feature of a substance, that the substance contains the logically necessary and sufficient conditions for that feature,

that these conditions are in theory intelligible, and therefore that the truth of the attribution of the feature to the substance is in theory discoverable in the nature of that substance. When he extends the substantial nature assumption to cover all features, he commits himself to a truth-conferring relation between a substance and its features; a feature is truly predicated of a substance if and only if the nature of the substance contains the complete reason of that feature.

As Leibniz began to refine his views about the relation between the attributes of God and their instantiation in the world in the spring of 1676, he took his first steps toward the development of the idea that truth is a matter of relations among concepts. In *On the Greatest of Things*, he notes the metaphysical significance of substances as subjects or bearers of predicates and of truth as grounded in the relation between substances and their states: “It is a wonderful fact that a subject is different from forms or attributes. This is necessary because nothing can be said about forms on account of their simplicity; therefore, there would be no true propositions unless forms were united to a subject” (A VI iii 514: Pk 69). Once he has hit upon the idea that a substance is a subject in which a modification of the divine attributes has been placed, and once he sees truth in terms of the relation between a subject and such attributes, the materials are in place for the concept containment theory of truth. That there is a close connection between his metaphysical views about self-sufficiency and his theory of truth is clear. In a text of 1676 we find one of his first attributions of completeness to substance: “A substance or complete Being is for me that which alone involves all things, or for the perfect understanding of which, no other thing needs to be understood” (A VI iii 400: Pk 109).

By the spring of 1676, the metaphysical underpinnings of the theory of truth are in place, including the claim that there is a hierarchy of subjects. First there is God, who is the subject of all simple attributes; then there are creatures, each of which is the subject of a partial expression of those attributes. According to Leibniz: “The essence of God consists in the fact that he is the subject of all compatible attributes” or forms while it is the nature of created “subjects” to be “conceived through forms” (A VI iii 514: Pk 69–71). Before creation the Supreme Being conceives the fully articulated essence for each individual substance. It follows that all true statements about the active things in the world will be statements about a substance as a subject and its relation to one of the predicates contained in its complete concept. In such a world all basic truths about the created world involve the inclusion

of a predicate in the concept of a subject. For Leibniz, all the truths about an individual substance are contained in its nature.

Against this metaphysical background, it is unsurprising that, when Leibniz began working on logical matters in his early years in Hanover, he concluded that all truths were a matter of concept containment. For Leibniz, all there is in the world are divine attributes and their combinations. In a striking passage of 1676, he acknowledges this point: “There is the same variety in any kind of world, and this is nothing other than the same essence related in various ways, as if you were to look at the same town from various places, or, if you relate the essence of the number 6 to the number 3, it will be  $3 \times 2$  or  $3 + 3$ , but if you relate it to the number 4 it will be  $6/4 = 3/2$ , or  $6 = 4 \times 3/2$ ” (A VI iii 523: Pk 83). In a world in which everything is constituted of combinations of divine attributes, it is not difficult to think of truth in terms of concept containment.

In April 1679 Leibniz produced a series of papers titled *On the Universal Calculus* that treat a number of questions related to formal validity and in which he first proposes a concept containment account of truth. Underlying these discussions is the idea that an affirmative categorical proposition is true just in case the concept of its predicate is contained in the concept of its subject. He takes true propositions to signify “nothing other than some connection between predicate and subject” in the sense that “the predicate is said to be in the subject, or contained in the subject” (A VI iv [A] 197: L 236). In the complexities of the logical papers of the late 1670s, we can discern the development of the fascinating view that a theory of truth for categorical affirmative propositions will settle the truth conditions for all propositions.

**SUBJECTS AND TRUTH IN THE DISCOURSE ON METAPHYSICS.** The *Discourse* of 1686 is also governed by the series of assumptions found in the early works about activity, self-sufficiency, identity, difference, and the nature of substance although some of the terminology has changed. The most original argument in the text concerns what scholars often call the *logical notion* of substance. This account is introduced in one of the most famous paragraphs in Leibniz’s writings. He begins §8 of the *Discourse* with a summary: “To distinguish the actions of God from those of creatures we explain the notion of an individual substance.” He then makes two new observations. First, he notes that “it is evident that all true predication has some basis in the nature of things and that, when a proposition is not an identity, that is, when

the predicate is not explicitly contained in the subject, it must be contained in it virtually.” Second, he suggests that from this account of truth it follows that “it is the nature of an individual substance or a complete being ... to have a notion so complete that it is sufficient to contain and to allow us to deduce from it all the predicates of the subject to which this notion is attributed” (A VI iv [B] 1539–1540). That is, an individual substance has a complete concept that contains all the predicates that can truly be predicated of it.

From these observations about substance Leibniz drew support for his doctrine of marks and traces: There must be something within each substance in virtue of which every predicate is presently true of it and which also provides the basis for the deduction of all the predicates that will ever be true of it, that is, traces of all the features that it has possessed in the past and marks of all those that it will possess in the future. He then begins § 9 of the *Discourse* by noting that “from this” account of substance follow “several notable paradoxes.” Among others he lists the indestructibility of substances and the identity of indiscernibles (A VI iv [B] 1541–42).

**SUBJECTS AND TRUTH IN FIRST TRUTHS.** Roughly four years after the *Discourse*, Leibniz wrote a brief essay, usually titled *First Truths*, in which he presents many of his core ideas in terse logical fashion. Although we now know that *First Truths* was written either during or soon after his year-long stay in Italy (A VI iv [B] 1643), scholars in the early part of the twentieth century assigned the text an earlier date (around 1686), and this encouraged the belief that his metaphysics developed out of his theory of truth rather than the other way round. But even if the metaphysics of substance came first, it is nonetheless significant that he came to see the theory of truth as so fundamental.

In *First Truths* Leibniz begins with the account of truth, explaining that in true propositions, the predicate is “always in the subject.” This *inclusion* means that all true propositions are identities, some of which are implicit and others explicit. That is, for some identities (for example,  $A$  is  $AB$ ), the inclusion in the subject is explicit; for others (for example, Alexander defeated Darius) it is implicit, and a more thorough analysis of the concept *Alexander* is required. He goes on to claim that “a wonderful secret” about the difference between necessity and contingency lies hidden here. He believes that contingency is a matter of implicit inclusion; necessity a matter of explicit inclusion. All truths are a priori in the sense that the concept of the predicate is contained in the con-

cept of the subject. But some of these truths are more explicit than others. Those that are not explicit are contingent. After presenting his theory of truth, he claims first that the principle of sufficient reason *directly follows* from it (A VI iv [B] 1645: AG 31). Having given an account of that principle, he runs through all the major tenets of his metaphysics as though they follow from these considerations. Consistent with the substantial nature assumption, he insists: “No created substance exerts a metaphysical action or influx on any other” because “what we call causes are only concurrent requisites” (VI iv [B] 1647: AG 33).

Leibniz’s claim that all true predication involves the containment of the predicate in the subject threatens to collapse the distinction between necessary and contingent truths. His stock response to this threat was to distinguish, as in the *Discourse*, between explicit and virtual containment or, as in *First Truths*, between explicit and implicit inclusion. But many critics (including Arnauld) have not been convinced. What does it mean to say that a predicate is contained in a subject virtually or implicitly rather than explicitly? His principal answer to this question, probably developed in the late 1680s in part as a reaction to Arnauld’s objections, relies upon a distinction between finite and infinite analysis. Necessary truths are those where the containment of the predicate in the subject is revealed after only finitely many steps of conceptual analysis; a corresponding analysis in the case of a contingent truth would require infinitely many steps and cannot be completed by any finite mind. Only God can see to the end of an infinite analysis. Though some scholars have suggested that this infinite-analysis account of contingency was later abandoned by him, it is to be found in the *Theodicy* (1710) and also in a letter to Louis Bourguet (1678–1742) written in the last year of his life.

Infinite analysis, though it provided Leibniz with a way of distinguishing necessary and contingent truths, raised difficulties for his project of developing the universal characteristic: If contingent truths required an infinite analysis to show that a predicate is contained in the concept of its subject, then even if conceptual connections could be represented numerically, the calculations required to demonstrate them could not be carried out, at least not by any finite mind. He seems largely to have given up on the project after 1690. In the *Monadology* he makes the distinction this way:

There are also two kinds of *truths*, those of *reasoning* and those of *fact*. The truths of reasoning are necessary and their opposite is impossible; the truths of fact are contingent, and their oppo-

site is possible. When a truth is necessary, its reason can be found by analysis, resolving it into simpler ideas and simpler truths until we reach the primitives.” (§33)

*First Truths* derives another typical Leibnizian doctrine, that there are no purely relational properties, from the concept-containment account of truth: “*There are not purely extrinsic denominations*. . . . For it is necessary that the notion of the subject denominated contain the notion of the predicate. And consequently, whenever the denomination of a thing is changed, there must be a variation in the thing itself.” Here the metaphysical presuppositions that lie behind the notion of substance as self-sufficient extend, through the theory that truth consists in conceptual containment, to cover all predications whatsoever. Another Leibnizian doctrine follows immediately: “Every individual substance contains in its perfect notion the entire universe and everything that exists in it, past, present, and future. For there is no thing on which one cannot impose some true denomination from another thing, at the very least a denomination of comparison and relation.” It is not surprising that presented with this text, Russell was inclined to see the theory of truth as the heart of Leibniz’s mature philosophy. But even in that text, he remarks of the claim that there are no purely relational properties that: “I have shown the same thing in many other ways, all in harmony with one another” (VI iv [B] 1646: AG 32–33).

UNITY AND AGGREGATES. For Leibniz, one of the main goals of the *Discourse* and related texts is to tempt philosophers such as Arnauld away from Cartesianism and toward the metaphysics of (what he will soon call) preestablished harmony. It is not surprising, therefore, that he is keen to note the various weaknesses of the Cartesian account of corporeal substance. As a means to this goal, he is concerned to show that something whose essence consists merely of *res extensa* is inadequate as a substance. He develops an argument for his account of corporeal substances that has roots in his early views and that highlights a weakness in the Cartesian account of corporeal substance.

Leibniz’s early assumption, captured in the principle of substantial activity, is that anything substantial will have its own principle of activity. He also believes that activity alone can generate self-sufficiency and unity. In 1676 he begins to connect self-sufficiency and completeness. He distinguishes substances or “complete things” from bodies or things “with figures.” In order to have a “perfect understanding” of a substance, one must only

understand the substance or “complete being” itself. But a “figure is not of this kind, for in order to understand from what a figure of such and such a kind has arisen, there must be a recourse to motion. Each complete being can be produced in only one way: that figures can be produced in various ways is enough to indicate that they are not complete beings” (A VI iii 400: Pk 115). In the 1680s he stresses that there will be something real in extension only if there are self-sufficient, unified things. He also begins to describe bodies as aggregates or collections of substances and to distinguish them from a real, single substance. He summarizes the point in 1690: “A BODY [*sic*] is not a substance but an aggregate of substances, since it is always further divisible, and any given part always has another part, to infinity.” Therefore: “It is contradictory to hold that a body is a single substance, since it necessarily contains in itself an infinite multitude, or an infinity of bodies, each of which, in turn, contains an infinite number of substances.” From this it follows that:

Over and above a body or bodies, there must be substances, to which true unity belongs. For indeed, if there are many substances, then it is necessary that there be one true substance. Or, to put the same thing another way, if there are many created things it is necessary that there be some created thing that is truly one. For a plurality of things can neither be understood nor can exist unless one first understands the thing that is one, that to which the multitude necessarily reduces.” (Foucher de Careil 319: AG 103)

Arnauld wonders what constitutes the difference between a corporeal substance or unity and an aggregate. In response Leibniz insists in his letter of April 1687 that some individuals are fundamental but others are not. The latter are aggregates, which are divisible, destructible, and temporary. They admit of degrees in the sense that they can be more or less unified and more or less divisible (e.g., a pile of rocks is more divisible than a piece of marble). The former are substances, which have a substantial forms, each of which creates a *living unity*. There is no reality to an aggregate above and beyond the reality of the entities that make it up. He insists that the unity that bodies or aggregates have is *imaginary*; a perceiving mind may see them as though they were a single thing. He writes to Arnauld that aggregates “have their unity in our mind only, a unity founded on the relation or modes of true substances” (G II 97: AG 86). Aggregates are logical constructions from modes and states of the entities aggregated.

As scholars have long noted, neither the *Discourse* nor the correspondence with Arnauld contains a clear account of exactly how a substantial form confers unity and identity on its substance. But the underlying assumption here, consistent with Leibniz’s original views about self-sufficiency and the unifying powers of mind-like things, is that a substantial form confers unity and identity on its substance by acting constantly in relation to its passive principle. In the 1680s he believed that the human soul acts on its body by *concomitance* where the idea is that the two act in perfect preestablished parallelism. He writes in 1690:

Hence, since I am truly a single indivisible substance, unresolvable into many others, the permanent and constant subject of my actions and passions, it is necessary that there be a persisting individual substance over and above the organic body. This persisting individual substance is completely different from the nature of body, which, assuming that it is in a state of continual flux of parts, never remains permanent, but is perpetually changed.” (Foucher de Careil 320: AG 104)

**MIND-BODY UNION AND PREESTABLISHED HARMONY.** There are reasons to believe that Leibniz understood the relation between mind and body in terms of preestablished harmony as early as the 1670s. But it is not until the texts of the 1690s that he put this account of union front and center. In *A New System of the Nature and Communication of Substances, and of the Union of the Soul and the Body*, published anonymously in the *Journal des Savants* in 1695, he offers his account as an improvement over that of Descartes. He explains that it was the problem of “the union of soul and body” that led him to reject Descartes’s philosophy and to recognize the need to “rehabilitate the substantial forms” (G IV 482–483: AG 142–143).

Here we have yet another approach to the core metaphysics, cleverly constructed to engage his audience—many of whom would have been quite interested in Cartesianism of one sort or another—on one of the weakest elements in the Cartesian system. The rhetorical hook here is that Cartesian dualism cannot adequately account for the mind-body union whereas preestablished harmony can. In the *New System* Leibniz declares that the great benefit of his metaphysics is that it offers a neat account of the world while at the same time explaining mind-body interaction. Because “it is not possible for the soul or any other true substance to receive something from without,” the mind acts out of its own “depths,” but

with perfect “spontaneity” and in perfect “conformity” to everything external to it, including the substances that make up its body. While each substance expresses the whole universe in its own way, the soul is related to the “organized mass that is its body” more “closely” than to other external things. Both the soul and the substances that constitute its body will express one another more closely than they do other “external” things. He concludes that this “hypothesis” displays “the marvelous idea of the harmony of the universe and the perfection of the works of God” (G IV 485–486; AG 143–144).

According to Leibniz the solution to the problem of the interaction between mind and body resides in the harmony constructed by God between the mind and its body. The mind wills to move its finger and the finger moves in perfect preestablished coordination. As he famously puts it, they are coordinated like two clocks constructed “from the start with so much skill and accuracy that one can be certain of their subsequent agreement.” Their “sympathy” is guaranteed by the “divine artifice” that has given each substance its “very own law ... from the beginning” (G IV 498–499; AG 148). In the *Monadology*, he writes: “According to this system, bodies act as if there were no souls (though this is impossible); and souls act as if there were no bodies; and both act as if each influenced the other” (G VI 621; §81).

## METAPHYSICS OF SUBSTANCE, MONADOLOGY

Scholars generally agree that by the time of the *Monadology*, Leibniz holds that the created world is constituted entirely of mind-like monads and that extended things are phenomenal. But there has been a good deal of discussion about when Leibniz gave up the extended substances of his youth. Some scholars have claimed that when he began to construct his own philosophical ideas they were based on a version of mental monism while others have dated the commitment to phenomenalism to the *Discourse* and the correspondence with Arnauld. Until all the writings of the period 1690–1716 have been thoroughly edited and published, there is little chance of solving this mystery. But whenever the phenomenalism begins, there can be no doubt that the notion of corporeal substance plays a key role in the *Discourse* and correspondence. Whether the passivity in such substances is constituted of extended force or collections of mind-like substances, there are corporeal substances constituted of active and passive principles. At some point after 1700, he seems to have become less convinced that the basic entities of the world should be modeled on organisms con-

ceived as combinations of substantial forms and passive principles. In the late 1690s, perhaps in response to criticisms leveled by Arnauld, he begins to emphasize the simplicity of substances, which he now sometimes calls monads, and to reduce everything in the world to these simple, mind-like monads and their perceptions. He writes to De Volder: “Considering the matter carefully, it must be said that there is nothing in the world except simple substances and in them, perception and appetite” (G II 270; L537).

**MONADOLOGY.** While he was in Vienna, Leibniz wrote this, the most famous of all his works, three years before his death. Written for a friend, he intended it as a summary of his philosophy. Although he did not publish it during his lifetime, generations of scholars have taken it to be the most complete and accurate account of his philosophy. He begins the work with a series of definitions: The monad is “a simple substance that enters into composites—simple, that is, without parts.” Monads are the “true atoms” or “elements” of nature and can form aggregates. The activities of monads are of two sorts; they have perceptions and appetitions. “The passing state which involves and represents a multitude in the unity or in the simple substance is nothing other than what one calls perception”; “The action of the internal principle which brings about the change or passage from one perception to another can be called *appetition*” (§14, §15). Although there is a good deal of discussion among scholars about the notion of appetition, it seems closely related to the *reason* or rule of action of the early period. It is the internal feature of the substance that drives it forward, determining its next state on the basis of its present state.

The monad itself may be taken to be another version of his original notion of substance as what is fundamentally unified and self-sufficient. In a related text of 1714, he explains that the Greek term “*monas* signifies unity, or what is one” (G VI 598; AG 207). While there is no doubt that many of the terms and some of the details are new, much of the text merely explicates standard Leibnizian doctrines. We find the various assumptions whose inspiration was originally Platonist. Each monad is an emanation of God, offers a unique perspective on the world, mirrors the universe, and is an indestructible and eternally active thing. He writes: “[Human] minds are images of the divinity itself, or of the author of nature, capable of knowing the system of the universe ... each mind being like a little divinity in its own realm” (§83). We find the commitment to the assumptions whose source was Aristotelian: The self-sufficiency of substance now makes

them *windowless*, but they constitute the fundamental entities whose natures anchor the theory of truth, the notion of a complete substance, the expression theory, the perfect coordination and harmony among things. Because each simple substance has its own entelechy, they can act as “the sources of their internal actions” (§18). Because “every present state of a simple substance is a natural consequence of its preceding state, the present is pregnant with the future” (§22).

Thus, the *Monadology* fits neatly into the sometimes subtle but always interesting evolution of Leibniz’s views about substance. From the late 1660s to the last years of his life, these fundamental entities constitute the basis for his account of nature. And regardless of the evolution of his ideas about substance, he persists in seeing them as a perfectly rational and divine ordained harmony.

## SUMMARY

Few thinkers in the history of philosophy have written so much, thought so deeply, and contributed so profoundly to so many areas. The vastness of Leibniz’s texts, the difficulty of his thought, and the quirkiness of some of his ideas make him both a difficult and delightful philosopher to study. As more and more of his works are published, there will be more gems to discover and more interconnections to discern. Not only does Leibniz offer profound philosophical insights, he is admirable as someone who thought deeply about the history of philosophy and the need for intellectual and political peace. As he wrote at the end of his life: “I have tried to uncover and unite the truth buried and scattered under the opinions of all the different Philosophical Sects, and I believe that I have added something of my own which takes a few steps forward. ... I flatter myself to have penetrated into the Harmony of these different realms” (G III 606: L 655).

### EDITIONS AND TRANSLATIONS

The standard of Leibniz’s original texts is the Academy edition (A above). The projected completion date is 2050. For a discussion of the editorial project, see Christia Mercer on “Gottfried Wilhelm Leibniz: *Sämtliche Schriften und Briefe*, edited by Akademie der Wissenschaften, Berlin: Akademie Verlag, 1923–, Series VI, volume 4,” in the *Times Literary Supplement* Oct. 18, 2002, 7–9.

Other than the Academy edition, the best editions of original texts are G and GM (above). Also helpful are:

#### Works

- Opera Omnia*. 6 vols., edited by Ludovici Dutens, Geneva: De Tournes, 1768. Reprinted, Hildesheim: Georg Olms, 1989.
- Leibniz’ Deutsche Schriften*. 2 vols., edited by G. E. Guhrauer, Berlin: 1838–1840.
- Nouvelles lettres et opuscules inédits de Leibniz*, edited by Alexandre Foucher de Careil. Paris: Ladrangue, 1857.
- Textes inédits d’après des manuscrits de la Bibliothèque provinciale d’Hanovre*. 2 vols., edited by Gaston Grua. Paris: Presses Universitaires de France, 1948.
- Leibniz Korrespondiert mit China: Der Briefwechsel mit dem Jesuiten Missionaren (1689–1714)*, edited by Rita Widmaier, Frankfurt: Klostermann, 1990.

Standard English-language translations of texts are L and AG (above) and the following:

#### Translated Works

- Selections*, edited by P. P. Wiener, New York: Scribner’s, 1951.
- New Essays on Human Understanding*, edited and translated by Peter Remnant and Johathan Bennett. Cambridge, U.K.: Cambridge University Press, 1981.
- De Summa Rerum: Metaphysical Papers 1675–1676*, edited by G. H. R. Parkinson. New Haven, CT: Yale University Press, 1992.
- Writings on China*, edited and translated by Daniel J. Cook and Henry Rosemont Jr. Chicago: Open Court, 1994.

## LENIN, VLADIMIR IL'ICH (1870–1924)

Lenin was a Marxist revolutionary, Russian Communist political leader, and major contributor to the philosophy of dialectical materialism. Although his mentor Georgii Valentinovich Plekhanov is considered the father of Russian Marxism, Lenin's distinctive version of the doctrine (later dubbed *Marxism-Leninism*) was considered authoritative by the Soviet Communist leadership and had an immense impact on Russia and the world through most of the twentieth century.

## LIFE

Lenin was born Vladimir Ilich Ulyanov into the family of a well-to-do school official in Simbirsk, Russia. He enrolled in the University of Kazan in 1887, the same year his elder brother Alexander was executed for involvement in a plot to kill Tsar Alexander III. Lenin was soon expelled from the university for taking part in student disturbances, but he gained admission to the University of St. Petersburg as an external student and in 1892 graduated with a degree in law. His activity in Marxist and other radical circles, beginning in 1888 in Kazan and Samara and continuing in St. Petersburg from 1893, led to his imprisonment in 1895, followed by banishment to eastern Siberia in 1897. Allowed to leave Siberia in 1900, he promptly fled to western Europe. For most of the next seventeen years he worked in various locations outside Russia, writing and conspiring with fellow Russian Marxists to promote the overthrow of the tsarist regime in their homeland.

From the time of the formation of the Russian Social Democratic Labor Party in 1898, Lenin worked tirelessly to gain control of the group and mold it into a militant Marxist revolutionary force. His ideas and aggressive political tactics brought him into bitter conflict with other leading Russian Marxists, including Plekhanov, but eventually his Bolshevik faction of the party became dominant (the Russian term *bol'shevik* means a member of the majority) and in continuing intraparty struggles he consolidated his position as both a theoretician and a leader. After the February Revolution of 1917 he was able, with the help of German military authorities, to travel to Petrograd, where in the October Revolution he led the Bolsheviks in seizing control of the Russian government. In power for six stormy years, marked by attempted assassination, civil war, famine, and the formation of the Union of Soviet Socialist Republics, Lenin suffered a series of strokes beginning in 1922 and died in January 1924.

## PHILOSOPHICAL WRITINGS

Lenin's philosophical activity extended from his student days to the Bolshevik revolution, and throughout this period its character was determined by his dogmatic materialism and his devotion to the theory and practice of Marxist social reconstruction as he understood it. His writings are strongly polemical in style, exemplifying the Leninist concept of *partiinost* (partisanship, party spirit) in philosophy.

Lenin first studied the writings of Karl Marx and his colleague Friedrich Engels systematically in 1888 and

1889. One of his earliest works, *What the "Friends of the People" Are and How They Fight the Social-Democrats* (1894)—directed against the Russian Populists, such as Nikolai Mikhailovsky—shows Lenin's general acceptance of dialectical materialism, the materialist conception of history, and the characteristic concepts of Marxist socialism. The distinctively Leninist element already evident is the strong emphasis on action, on the need to combine theory with revolutionary practice. Lenin asserted that the objective, necessary character of the laws of social change in no way destroys the role of active individuals in history. Thus, unlike those Marxists who feared that Russia was not sufficiently developed for a socialist revolution, Lenin stressed the need for expeditiously organizing the revolution, focusing on the proletariat (not the peasantry) as the leading revolutionary class. This activist approach was carried further in subsequent writings, chiefly *What Is to Be Done?* (1902)—the first work in which he used the pseudonym *Lenin*—and *One Step Forward, Two Steps Back* (1904). In both of these works Lenin elaborated the need for a clandestine, militant, centralized, highly disciplined party to unify and direct the proletariat.

Lenin's book *Materialism and Empirio-Criticism* (1909)—the principal philosophical work published during his lifetime—is directed against a group of Russian writers, including Alexander Bogdanov and Anatoly Lunacharsky, who attempted to supplement Marxism with the phenomenistic positivism of Richard Avenarius and Ernst Mach. Characterizing their position as a form of subjective idealism (and thus as inimical to Marxism), Lenin defended dialectical materialism on the chief points at issue, particularly the status and character of matter and the nature of knowledge. Opposing the view that matter is a construct of sensations, Lenin argued that it is ontologically primary, existing independently of consciousness. Likewise, space and time are not subjective modes of ordering experience but objective forms of the existence of matter. Opposing the view that discoveries of modern science cast doubt on the objectivity of matter, Lenin distinguished between scientific conceptions of matter, which are provisional and relative because no constituent of a material thing can be regarded as indivisible or irreducible, and the philosophical conception, according to which matter is simply the objective reality known to our senses. The only property of matter to which philosophical materialism is committed, according to Lenin, is the property of existing objectively. In epistemology, Lenin opposed the so-called hieroglyph theory of Plekhanov, according to which sensations are signs of an external reality that they do not

necessarily resemble, and developed a strictly realist position, the copy theory, according to which sensations depict or mirror the real world. On this basis Lenin defended the possibility of objective truth, emphasizing practical experience as its test.

Dialectics, which Lenin had long considered the heart of Marxism, is treated most fully in *Philosophical Notebooks* (1933), a posthumous compilation of notebook entries and fragments dating chiefly from 1914 to 1916, including his extracts from, and comments on, a number of works by other thinkers, above all Georg Wilhelm Friedrich Hegel's *Science of Logic*. Lenin showed a high regard for the Hegelian dialectic, which he found thoroughly compatible with materialism, and he asserted that dialectics, logic, and the theory of knowledge are identical. In his conception of dialectics Lenin departed from Engels in laying the greatest stress not on the transition from quantity to quality but on the struggle of opposing (contradictory) forces or tendencies within every natural object and process; Lenin saw this struggle as the internal basis of all change, and thus as the core of dialectics.

Lenin's last major works are concerned mainly with economic and political aspects of the revolutionary transition from capitalism to communism. In *Imperialism, the Highest Stage of Capitalism* (1917) he argued that capitalism had reached its final, monopolistic phase and was ripe for overthrow, but that, because of the uneven development of capitalism in different countries, socialism would not triumph in all or most countries simultaneously, as Marx had expected. In *State and Revolution* (1918), directed against the supposed opportunism of Marxist rivals such as Plekhanov and Karl Kautsky, Lenin elaborated on the Marxist thesis that the state is an instrument of class domination. He laid special stress on a number of points not fully developed by Marx or Engels: One was the need for shattering the bourgeois state machinery and establishing a proletarian state or dictatorship of the proletariat, and another was the distinction between the lower phase of communism, in which people are rewarded in proportion to the work they perform and the state is still needed to repress remnants of the former exploiting classes, and the higher phase, in which rewards are proportional to peoples' needs and the state will wither away because all class antagonisms have been eliminated.

## INFLUENCE

Throughout the twentieth-century Communist world (including China), Lenin was regarded as a philosophical

luminary of the first magnitude. In the Soviet philosophical pantheon, he was considered the greatest thinker in history after Marx. Formal education in philosophy in Russia under Communist rule was structured on the premise that Lenin's pronouncements were beyond criticism; his writings were published in vast editions in all major and many minor languages, making him the most widely published philosophical thinker of the twentieth century. In one sense he was also the most influential: Although his conceptual contributions to the development of philosophy as an intellectual discipline were negligible, his ideas provided the impetus and the rationale for policies that materially and often tragically affected the lives of millions of people.

The attack on Stalinism begun by Nikita Khrushchev in 1956 did not immediately disturb the cult of Lenin, whose principles Joseph Stalin was said to have betrayed, not implemented. With the introduction of *perestroika* in the mid-1980s under Mikhail Gorbachev, however, significant responsibility for the flaws and evils of the Soviet system was traced back to Lenin himself; in particular, his theory of imperialism and his fixation on class antagonisms to the neglect of common human interests and moral values were criticized at the highest levels. When the Soviet Union collapsed at the end of 1991, the Communist Party lost political power and Lenin's philosophical authority all but evaporated in Russia and the former Soviet bloc. Thereafter, educational curricula in Russia and Eastern Europe were reworked to eliminate the vestiges of Marxism-Leninism, and the publication of Lenin's writings ceased.

## LEONARDO DA VINCI

(1452–1519)

Leonardo da Vinci, the Florentine artist, scientist, and inventor, was born at Vinci in Tuscany, the natural son of a notary, and died near Amboise, France. At his death he left a sizable collection of notebooks that were subsequently scattered in the various libraries of Europe. From 1881 on, many of these notebooks have been published. They consist of notes and jottings on various topics: mechanics, physics, anatomy, physiology, literature, and philosophy. They contain, moreover, plans and designs for machines that frequently have suggested Leonardo's "precursive genius." There are machines of war and of peace, flying machines based on the flight of birds, a parachute, a helicopter, tools and gadgets of all kinds. Leonardo's notebooks are also full of methodological notations on the procedures of scientific inquiry and philosophical considerations about the processes of nature. Undoubtedly many of the arguments that he discussed were taken from the philosophical literature of the time, especially from the writings of the Ockhamists; however, a coherent and complete philosophical scheme cannot be found in the notes, whose chronological order is extremely uncertain. Pierre Duhem held that Leonardo was mainly inspired by the doctrines of Nicholas of Cusa, but recent studies tend to emphasize his dependence on Marsilio Ficino. Leonardo lived in Florence for the first thirty years of his life and subsequently returned there many times.

Leonardo's *Treatise on Painting* (published 1651) reveals the artist and the scientist united in one personality. Painting, which he placed above all other arts, aims at representing the work of nature to the senses. Thus it extends to the surfaces, the colors, and the forms of natural objects, which science studies in their intrinsic forms. The beauty that painting seeks in things is the proportion of the things themselves, and proportion is also the object of the scientific consideration of nature. According to Leonardo, understanding nature means understanding the proportion that is found not only in numbers but also in sounds, weights, times, spaces, and any natural power

whatever. Both art and science have the same object, the harmonious order of nature, which art represents to the senses and science expresses in its laws.

Leonardo held that the two pillars on which science stands are experience and mathematical calculation. As an “unlettered man” (as he called himself) he had contempt for those who, instead of learning from experience, claimed to learn from books (the commentators and followers of Aristotle). He contrasted his work as an inventor with their work of “trumpeting and reciting the work of others.” “Wisdom is the daughter of experience,” he said. Experience never deceives, and those who lament its deceitfulness should lament their own ignorance because they demand from experience what is beyond its limits. The judgment of experience can be mistaken; and the only way to avoid error is to subject every judgment to mathematical calculation and to use mathematics unrestrictedly to understand and demonstrate the reasons for the things that experience manifests. Mathematics is therefore, according to Leonardo, the basis of all certitude, since without recourse to mathematics it is impossible to put an end to the verbal disagreements of what he called the sophistic sciences—that is, the philosophical disputes about nature.

The privilege accorded to mathematics was most certainly a legacy from Platonism. Leonardo took from Plato’s *Timaeus* and Ficino’s commentary on it the doctrine that the elements of natural bodies are geometric forms; thus the efficacy of mathematics as an instrument of investigation was justified for him by the fact that nature itself is written in mathematical characters and that only those who know the language of mathematics can decipher it. This is the major contribution that ancient Platonism made to the formation of modern science. Nicolas Copernicus and Galileo Galilei shared this obviously metaphysical doctrine that, however, strongly contributed to launching science from its origins to its mathematical organization. It helped bring scientific consideration from the domain of quality (of natures or essences) to that of quantity by permitting consideration of the natural object as measurable; that is, in the extremes, by reducing the objectivity of nature to its measurability.

However, if the order of nature is a mathematical order, then it is a necessary order; and this necessity is, according to Leonardo, the only true “miracle” of nature: “O wondrous and awesome necessity! With your law you constrain all effects to result from their causes by the shortest path, and according to the highest and irrevocable law every natural action obeys you with the briefest

operation.” The phrases “by the shortest path” and “with the briefest operation” refer to another feature of the necessary order of nature: its simplicity. Nature follows the shortest or simplest path in its operations. It does not like useless loitering, and this also reveals the mathematical character of its structures. Necessity and simplicity of nature exclude the presence of arbitrary or miraculous forces, as well as the efficacy of magic and of those forces to which it appeals.

Guided by these criteria, Leonardo could arrive at and formulate important theorems and principles of statics and dynamics. The theorem of the composition of forces, the principle of inertia, and the principle of action and reaction are the most notable of these formulations, which, of course, he did not state in the precise form that they received later from René Descartes and Isaac Newton. Nevertheless, they demonstrate his genius for moving from the limited work of the inventor to the generalizations of the scientist.

### Bibliography

Leonardo’s manuscripts have been published with photographic reproductions by Charles Ravaisson-Mollien, 6 vols. (Paris, 1881–1891). They have also been published in *Codex Atlanticus*, edited by G. Piumati (Milan, 1894–1904) and *I manoscritti e i disegni di Leonardo da Vinci*, published by the Reale Commissione Vinciana (Rome, 1923–1930). The best collection of selections is J. P. Richter, *The Literary Work of Leonardo da Vinci*, 2 vols. (London, 1883; 2nd ed., 1939). *Leonardo da Vinci on Painting: A Lost Book*, edited and translated from the *Codex Vaticanus Urbinas*, No. 1270, and from the *Codex Leicester* by Carlo Pedretti (Berkeley: University of California Press, 1964), includes a preface by Kenneth Clark and some material never published before. Works on Leonardo include the following: Pierre Duhem, *Études sur Leonardo da Vinci*, 3 vols. (Paris, 1906–1913); E. Solmi, *Leonardo* (Florence, 1900); C. Luporini, *La mente di Leonardo* (Florence: Sansoni, 1953); Eugenio Garin, *Medioevo e Rinascimento* (Bari: Laterza, 1954), pp. 311ff., and *Cultura filosofica del Rinascimento italiano* (Florence: Sansoni, 1961), pp. 388ff.; I. B. Hart, *The World of Leonardo da Vinci* (London: Macdonald, 1961); James Beck, *Leonardo’s Rules of Painting: An Unconventional Approach to Modern Art* (New York: Viking Press, 1979); and Boris Kouznetsov, “The Rationalism of Leonardo Da Vinci and the Dawn of Classical Science,” *Diogenes* (69 [1970]: 1–11).

## LEONT'EV, KONSTANTIN NIKOLAEVICH (1831–1891)

Konstantin Nikolaevich Leont'ev was a Russian writer, philosopher, critic, and publicist. Like almost all important nineteenth-century Russian authors, Leont'ev came from a family of landowners. He was trained in medicine at the University of Moscow and served for three years as an army doctor in the Crimean war. After the war he took the post of family doctor on a country estate in the province of Nizhnii-Novgorod, married, and published his first novel, *Podlipki* (1861). In 1863 he entered the Russian diplomatic service and worked for eight years as a consular official on the island of Crete and the Balkans. After a cure from dysentery, he underwent a spiritual crisis and spent a year (1871–1872) in a Greek monastery on Mount Athos. Soon after he left the consular service, and he returned to Russia where he worked as a journalist in various cities and a censor of literature in Moscow. In 1887 he decided to renounce the secular world, was officially divorced from his wife, and retired to the Optyna Pustyn' cloister in the province of Tula. Shortly before his death he took monastic vows and died a monk in the Trinity-St. Sergius Monastery near Moscow.

Although Leont'ev can be considered one of the brilliant representatives of nineteenth-century Russian culture, on a par with Alexander Herzen, his work is not very well known. His novels and stories have hardly been translated and his philosophical and political views only scantily studied. The main reason for this seems to be his odd, maverick-like personality, which expressed itself in views so paradoxical and extreme that it is almost impossible to weld them together and to integrate them with the main ideas of his age.

Leont'ev was torn between an amoral aestheticism and the intense desire for saving his soul by the ascetic renunciation of the world. The protagonist of almost all his novels (among which, apart from *Podlipki*, *V svoem kraiu* [In my own land, 1864], and *Egipetskii golub'* [The Egyptian dove, 1881–1882]) is a narcissistic superhero (more or less identical with Leont'ev himself) who takes delight in all things beautiful and considers it his duty to lead a poetic life. "Ethics does not coincide with aesthetics: otherwise it is impossible to approve the beauty of Alcibiades, of a diamond, of a tiger." Which is better: "the bloody and spiritually exuberant age of the Renaissance, or contemporary Denmark, Holland, Switzerland—humble, prosperous, moderate?" (*Sobranie sochinenii*, Vol. I, p. 282; 414). However, the hero is dissatisfied with

his actual self as he realizes his own limitations and the vanity of his sensuous experience and of the world he has enjoyed so much.

It is this latter attitude that made Leont'ev severely criticize contemporary writers such as Fëdor Dostoevsky, Lev Tolstoy, and Vladimir Solov'ev. In the essay "*Nashi novye khristiane: F. M. Dostoevskii i graf Lev Tolstoi*" ("Our new Christians: F. M. Dostoevsky and Count Lev Tolstoy, 1882) he ridiculed the *rose-colored Christianity* of these authors. By promising paradise on earth (just like the utopian socialists), Leont'ev stated, they introduced heretical, humanistic elements into their religious views, making God a diluted God of love instead of a God of fear. However, in another essay he made a brilliant analysis of Tolstoy's novels, in particular praising *War and Peace*.

Leont'ev is best known for his aesthetic approach to history and his uncompromising criticism of his own age, which according to him, was dominated by equality and its unavoidable counterpart mediocrity. Just as such thinkers as de Maistre, Comte Joseph de Maistre, Thomas Carlyle, Friedrich Nietzsche, and John Stuart Mill, Leont'ev rejected the industrial revolution of the nineteenth century, which had led to democracies in which there was no place for great men and intense, *creative* contradictions. In his collection of essays *Vostok, Rossiia i slavianstvo* (The East, Russia, and Slavdom, 1885–1886), which included his main work "*Vizantizm i slavianstvo*" (Byzantinism and Slavdom, 1875) he developed a *biological* theory of the evolution of history. Each historical cycle comprises three periods: a period of childhood, or *primitive simplicity*; a second period of adulthood, characterized by differentiation and *flourishing complexity*; and a final period of old age, which through decline and disintegration leads to a *secondary simplicity*.

According to Leont'ev Europe was already in its third phase, the first being the period of the barbarian invasions, the second the High Middle Ages. As clear signs of the contemporary decay, he considered the disappearance of class distinctions and the dominance of bourgeois culture, the culture of the *average man*. Since the time of Peter the Great (1672–1725), this European *leveling interfusion* had infected Russia. Russia's salvation, he maintains, lies in reversing this process, which can only be done by defending its prime institutions, autocracy and orthodoxy, and promoting a situation in which "despotism, danger, strong passions, prejudices, superstitions, fanaticism ..., in a word everything to which the nineteenth century is opposed" (*Sobranie sochinenii*, Vol. VIII, p. 98) could flourish. More extreme and reactionary than

the older Slavophiles such as Aleksei Khomiakov and the brothers Ivan and Petr Kireevskii, Leont'ev had no scruples about supporting strict censorship and political repression in order to reverse the *pernicious* process of democratization. However, he with great insight foretold the excrescences of the “fixed equality” of communism, which “through a series of combinations with other principles must gradually lead, on the one hand, to a decreased mobility of capital and property, and, on the other, to a new juridical inequality, to new privileges, to restrictions on individual freedom, and to *compulsory* corporate groups, clearly defined by laws—probably even to new forms of personal slavery or serfdom.” (Edie, Scanlan, Zeldin 1965, p. 278).

Leont'ev is often called the Russian Nietzsche. With his pessimistic view on the development of European culture and society, he can be seen as a forerunner of Oswald Spengler. In Russia interest in his work has grown considerably since the 1990s. Biographical data, his complete works, and criticism about him (in Russian) can be found on the web at <http://knleontiev.narod.ru>.

## LEOPARDI, COUNT GIACOMO

(1798–1837)

Count Giacomo Leopardi, the Italian poet and prose writer, was one of five children born to Count Monaldo Leopardi and Marquise Adelaide Antici, in Recanati, near Ancona. His brief and anguished existence was plagued both by continuous illnesses (among them rachitis, which made him a hunchback) and the bigotry of his parents, who refused him financial support. A liberal and an agnostic, he yearned to leave the “bodiless, soulless, lifeless” ancestral abode where he had spent all his time devouring books; learning Latin, Greek, Hebrew, and a number of modern languages; and translating and writing critical essays on the classics, history, and astronomy. A fellow philologist, Pietro Giordani, opened to him the world beyond his “savage native town.” Afterward, he traveled to Rome, Milan, Bologna, Pisa, Florence, and Naples, never venturing beyond the Alps because of his frail constitution, and even refusing the Dante Alighieri chair offered to him by the University of Bonn. Often he returned to Recanati, only to leave after a short stay. Nature and beauty offered him moments of precious calm, but these few instants could not dispel the physical and metaphysical oppression that, for Leopardi, seemed to weigh upon the world. Everywhere reality proved a bitter disillusionment. Several devoted publishers and friends offered him various jobs and forms of subsistence, but generally to little avail. The poet both expected and invoked death, which came to him in Naples in 1837, shortly after he had dictated his last poem.

### THE CANTI

As Elme Marie Caro said, Leopardi wanted to be, deserved to be, and was a philosopher. He did not come to philosophy through poetry, or to poetry through philosophy; his poetry is his philosophy. While Leopardi's prose works (the magnificently cogent *Operette morali*, 1827; the diary called the *Zibaldone*, 1898–1900; and the copious correspondence, or *Epistolario*, published posthumously) reflect the melancholy meditations of a thinker concerned with universal sorrow, the most fulfilling expression of his thoughts is to be found in his poetry, the *Canti* (1831, 1835, 1845). The *Canti* complement and complete the *Operette*, because in expression and content they constitute an organic outgrowth of the nature and orientation of Leopardi's philosophy.

## PESSIMISM

Leopardi's philosophy, which should not be viewed as a methodically pondered and presented system, has been labeled skeptical and pessimistic, a philosophy of despair. Indeed, it dwells upon the triumph of evil over good and of nature over man, the mystery and insignificance of our mortal existence, the anguish of our miseries, the extinction of youth, and the lure of death. As Arthur Schopenhauer recognized, "No one has treated these subjects more fundamentally and exhaustively in our day than Leopardi." Given the limited dissemination of Schopenhauer's *Die Welt als Wille und Vorstellung* (1819) at that time, it is unlikely that Leopardi read the work or that he met the author. It is certain, however, that Schopenhauer read Leopardi's poems; yet while he mentions them, he in no way indicates whether they influenced the development of his own thought.

Yet the similarities run deep. Leopardi characterized life—this life we love, not for itself but, erroneously, for its promise of happiness—under the rubrics of sorrow (*dolore*), or unhappiness (*infelicità*), and tedium (*noia*). By means of this perspective, he was able to discard many cherished notions. Assuming the hapless state of humanity, the notions of patriotism and heroism vanish as follies, as does the glory of genius, which the poet had once assiduously pursued and which later, like Eduard von Hartmann, he relegated to the category of illusions. As for love and beauty, they entice soul and senses cruelly, since their ephemerality brands them as colossal deceptions. Nature, which according to Leopardi is the mysterious principle of being, closely related to Hartmann's concept of the Unconscious as a neutral absolute, answers none of man's queries about the secret of things; it is undecipherable, mechanical, unreasoning and unreasonable, and at times brutally hostile toward men. Man, then, is nothing; if he is something, he is so by virtue of being his own greatest enemy. In the *Operette morali*, Schopenhauer's gloomy picture of life as a gory chase in which men scramble for spoils differs only moderately from Leopardi's description of Prometheus's and Momus's journey.

Death as nonbeing is therefore, like love during its moment of existence, a thing of beauty. Death as suicide, however, solves nothing because it constitutes not a negation of existence but rather, as Schopenhauer asserted, an act directed against the accidental portion of unhappiness that creeps into human existence. Moreover, the future holds no promise, and *progress* and *perfectibility* are empty words.

## EVIL

Leopardian pessimism differs from Schopenhauer's on two questions: the principle of evil and the remedy of evil. Leopardi refused to consider the problem of the necessity of evil and, in any case, would not have ascribed evil to a principle, such as Will or the Unconscious, simply because he believed that evil is an empirical datum and does not require metaphysical or transcendental explanation. He felt the existence of evil and saw only gross arbitrariness in those who attempt to show why it must exist, or who make a transcendent dialectics of the universal law of suffering. Historical pessimism, which stems from the "restless creative mind" of men who boldly oppose unconquerable nature, and cosmic pessimism, through which evil, inherent in nature, subjugates man, are fundamentally interrelated in Leopardi's philosophy and preclude all thought of remedy. The individual's only recourse is stoic dignity—resignation, silence, and scorn. "Of what value is our life, except to despise it?" In this respect, Leopardi was a precursor of German pessimism.

Schopenhauer also upheld Stoic dignity, but for Leopardi dignity was less a remedy for suffering than an instinctive and protective reaction that neither alters suffering nor consoles the sufferer. Schopenhauer even found some consolation in the Buddhist ideal of nirvāṇa, which Leopardi could not. And while Schopenhauer could derive a sense of pride from his belief that the more developed the organism, the greater its misery, Leopardi, even when speaking of man's nobility, could not find in it any basic gratification. The degree to which both men felt a sense of compassion differed: Leopardi's pity, although less central to his ethics than *Mitleid* was to Schopenhauer's, was still less condescending and more sympathetic than Schopenhauer's.

Leopardi held to the inexorability of destiny and nature's blind subservience to it—subservience which fails to take into account man's struggle and misery. Everything, therefore, is deceit; the only truth lies in nothingness. For Leopardi, what counts is the philosophical negation of life, both in its effective pains and in its false felicities. Only in this way can one claim to demonstrate moral consistency—through the affirmation of a negative totality.

## ILLUSIONS AND REALITY

Reason, then, in Leopardi is tantamount to negation. Illusions are merely dreams, substances insofar as they may be considered "essential ingredients" of living, "half-real things." Since all that is real comes to nothing, Leopardi

inverted the concept of reality and asserted that only the illusory is real. In claiming this, he did not suggest that reality is a mere phenomenon concealing a noumenon. On the contrary: The reality of the world in which man lives and which has meaning for him is neither rational nor spiritual, but natural and imaginary; it is a reality that is necessarily maintained by what we call illusions. Beyond it lies complete negation. Hence Leopardi professed the opposite of the instinctive noumenalism of man's mind. The world is real in relation to the absence of those other substances that we seek under the heading of truth. Just as the world is arbitrary, so men's beliefs, desires, hopes, and "certainties" (justice, science, virtue, freedom, idealism) are merely groundless illusions. Leopardi despised theological, dogmatic, spiritualistic philosophies, along with any form of presumptuous optimism.

## RELIGION

The philosophy outlined above precluded religious faith. Leopardi might assent to the Scriptures' theory of man's decadence, but he could not admit Christian Providence or the Resurrection. Yet although he is unhappy (*infelice*), the poet is not irreligious. His "atheism" bespeaks the combined awareness of the necessity and of the absence of God—in short, of the impossibility of hope. Escape into pleasure is self-deceiving ("pleasure is a subjective speculation and is unreal"), for we seek the idea of pleasure more than we seek pleasure itself; indeed, the latter does not exist. The resulting tedium closely approaches Martin Heidegger's *Angst*, which reflects the experience of nothingness.

## VALUE OF LIFE

Because Leopardi is an artist and poet, the immensity of his despair loses its bitterness in a melancholy and fraternal contemplation of existence. Despair allows him to understand the value of human life, although in the long run life is a "useless misery." As a measure of exiguous man's infinite desires against the infinity of being, tedium itself (that is, enthusiasm, heroism, and desperation successively experienced and resulting in a sense of nothingness) seemed to him "the greatest sign of grandeur and nobility in human nature." He recognized illusion as a positive value, offsetting negation and "the infinite vanity of all things." This kind of deception is of value to man, since it constitutes his only justifiable pleasure. Despite it, or actually because of it, Leopardi called for brotherly solidarity and compassion, not out

of love of God, but out of a desire to combat the cruelty of destiny and of nature.

What Leopardi finally did was to negate negation, thus creating what he called an ultraphilosophy. He developed a philosophy about philosophy (namely, that we should not philosophize) that rejects reason. For, wrote Leopardi, "As [Pierre] Bayle said, in metaphysics and morals reason cannot edify, only destroy." But by denying itself, reason in a sense vindicates its own power and worth. While exposing the pains and infirmities of existence, Leopardi makes us love the very objects of his despair. By glorifying illusion, art, in the pureness of its beauty (which supersedes the misery of all material things), becomes the most important postulate of ultraphilosophy. Art transfigures sorrow and, by not limiting its own strength and freedom, converts that sorrow into human greatness—a greatness that constitutes the triumph of free creative power and of infinite strength.

LEQUIER, (JOSEPH LOUIS)  
JULES  
(1814–1862)

(Joseph Louis) Jules Lequier, or Léquyer, the French philosopher, was born at Quintin in Brittany. He was educated there and in Paris at the *collège* of St. Stanislas and the École Polytechnique. An intensely religious though extremely heterodox Roman Catholic, Lequier devoured the literatures of philosophy and theology, and although none of his own work was published during his lifetime, he wrote voluminously and also translated Sir Humphry Davy's autobiography. Jean Wahl has made interesting comparisons between certain aspects of the thought of Lequier and Søren Kierkegaard, although neither could actually have influenced the other. However, Lequier directly influenced Charles Renouvier, who always considered him his "master in philosophy," and through Renouvier he attracted the attention of William James. Renouvier later published Lequier's book, *La recherche d'une première vérité* (Paris, 1865).

Lequier's philosophy aimed at but never achieved systematic wholeness; its essential theses, however, may be restated in four interrelated doctrines. First, Cartesian methodological doubt must be genuine, not feigned, and unless it is employed in good faith, one is likely to err in doubting real evidence, just as, without methodological doubt one is likely to err in allowing unwarranted belief. Accordingly, doubt has no privileged status over belief. Ability to attain truth as well as falsehood must underlie the quest for truth, and freedom is thus a condition of the possibility of knowing truth as well as of being mistaken.

Second, freedom is a "double dilemma." Either causal necessity or freedom is a fundamental truth, and each doctrine must be asserted either necessarily or freely. If necessity is the true doctrine, my affirmation thereof is *eo ipso* necessary, but since neither doubt nor belief relative to evidence would function in that determination, doubt results. If necessity is true but I affirm freedom, then in addition to my inconsistency (for my affirmation is made necessarily), there is only a subjective foundation for knowledge and morality. Given the truth of determinism, erroneous as well as true judgments are necessary, and any supposed distinction between them is illusory. According to the hypothesis of freedom, if I freely affirm global necessity I am fundamentally inconsistent. Finally, if I affirm freedom under the same hypothesis, not only is my affirmation consistent with the hypothesis but I have a foundation for knowledge and morality. Under the

double dilemma, the only satisfactory alternative is freely to affirm freedom—Lequier's "first truth." Freedom is essentially the power to add some novel reality to the existing world. Causality must be explained through freedom and not vice versa.

Third, the data that are present to a given event of consciousness arise out of the past relative to that event; they are past actualities but present potentialities for the internal character of that event of consciousness out of which a determining decision is made. Human consciousness is a succession of self-creative events, each of which is given its ancestor selves as well as other data, and each of which is partially *causa sui*, a "dependent independence." Thus, the totality of causal conditions of any human experience does not make this experience necessary, but only possible, while internal decision makes it contingently actual. All choice-making contains some arbitrary element.

Fourth, in extending these doctrines to theology, and taking as axiomatic the concept that freedom, responsibility, and moral and religious values depend upon choice-decisions, Lequier holds that an omniscient God need not know future contingents, since, in relation to any divine experience, they are not yet existent. To be knowable is to be determinate, and if all were known "from eternity," then all would be eternally determinate, and time and choice-making would be illusions. Also, since contingents are unequivocally in part *causa sui*, they are not wholly dependent on divine power. Far from viewing divine power as absolute total control, Lequier insists that the only power worthy of God is the far greater one of creating self-creators. Real choice in the world is incompatible with all-embracing necessity, and it is neither metaphysically requisite nor religiously desirable that God be wholly immutable and eternal. God must have a temporal aspect in order to come to know contingents as they are realized; thus he remains always omniscient in knowing all there is to know. Lequier's theology is thus that of an eternal-temporal being, his omniscience and omnipotence being relative to the irreducible contingency and self-creativity in the world.

Lequier's philosophy bears various striking resemblances to themes in Samuel Alexander, Henri Bergson, Nikolai Berdyaev, Émile Boutroux, William James, Kierkegaard, C. S. Peirce, and A. N. Whitehead.

## LE ROY, ÉDOUARD

(1870–1954)

Édouard Le Roy, the French philosopher of science, ethics, and religion, was born in Paris and studied science at the École Normale Supérieure. He passed the *agrégation* examination in mathematics in 1895 and took a doctorate in science in 1898. Le Roy became a *lycée* teacher of mathematics in Paris but was soon drawn to philosophical problems through an interest in the philosophy of Henri Bergson. He succeeded Bergson, to whose thought his own was deeply indebted, as professor of philosophy at the Collège de France in 1921 and was elected to the French Academy in 1945.

In a series of articles titled "Science et philosophie" (*Revue de métaphysique et de morale* 7 [1899]: 375–425, 503–562, 706–731, and 8 [1900]: 37–72), Le Roy took a pragmatic view of the nature of scientific truth, a view more or less shared by his contemporaries Bergson, Jules Henri Poincaré, and E. Wilbois. Scientific laws and even scientific "facts," Le Roy maintained, are arbitrary constructs designed to meet our needs and to facilitate effective action in pursuit of those needs. Scientific reason, in other words, distorts reality in the interests of practical action. The scientific facts on which induction is based are artificially extracted from the continuous flow of happenings and experiences and built up into convenient (rather than "true") thought structures, which constitute "the grammar of discourse" and enable us to talk about, and deal with, what would otherwise be "the amorphous material of the given." Thus, in reacting against scientific

mechanism, Le Roy presented an extreme view of mind as the creator of its own reality.

Le Roy took the same pragmatic view of discursive religious truth in *Dogme et critique* (Paris, 1906). His views were supported by the Catholic modernists and condemned as dangerous in a papal encyclical. Le Roy held that the validity of dogmas cannot be proved, nor do they profess to be provable; they depend upon a rigid and externally imposed authority; their expression and frame of reference is that of medieval philosophy; and they are alien to, and incompatible with, the body of modern knowledge. For these four reasons they are unacceptable to the modern mind as truths. Nevertheless, they possess a pragmatic value; they fulfill a purpose, in this case a moral one. "Although mysterious for the intelligence in search of explanatory theories," Le Roy held, "these dogmas lend themselves nonetheless to perfectly specific formulation as directives for action." Christianity is thus not a system of speculative philosophy, but a set of stated or implied injunctions, a way of life. For example, the belief in a personal God demands that our relation to him resemble our relation to a human person. The doctrine of the resurrection of Christ teaches that we should behave in relation to him as if he were alive today.

Le Roy's misgivings concerning religious dogmas arose because the dogmas seemed to him irreconcilable with a homogeneous system of rational knowledge. In a pragmatic and relativist conception of truth such incompatibility should not be significant. However, the criterion of truth, for Le Roy, was neither use nor coherence, but "life" itself, dynamic and self-developing. Scientific theory is useful distortion, religious teaching a source of moral action, and both are arbitrary in their choice of concepts and symbols. Genuine knowledge is a kind of self-identification with the object in its primitive reality, uncontaminated by the demands of practical need. Intuition, not discursive thought, is the instrument of such knowledge, and the criterion of truth is that one should have lived it; otherwise, according to Le Roy, one ought not to understand it. This, as L. Susan Stebbing rightly pointed out, altogether removes the criterion from rational criticism, since life is both truth and the criterion of truth.

Le Roy's philosophy culminated in moral and religious concerns, as is seen in Volume 2 of his posthumously published *Essai d'une philosophie première* (2 vols., Paris, 1956–1958). His position is similar to Bergson's in *Les deux sources de la morale et de la religion*. The élan vital that animates us takes the form of an "open," that is, indeterminate, moral demand. This generalized

obligation is the essence of the self as a free and self-creating agent. Le Roy stated that “to believe is to perceive a spiritual exigency and to act under its inspiration.” The open nature of the exigency “beyond any ideal capable of being formulated” places Le Roy’s view in the same category as much recent morality of authenticity. The agent is constantly transcending the determinate in the direction of some necessarily unspecified self-fulfillment. Because morality implies precepts and precepts imply universalizability, the notion of a morality that cannot be formulated would seem to be self-defeating. In his conception of a moral quest Le Roy, in fact, seemed to presuppose the Christian values to which he subscribed.

## LE SENNE, RENÉ (1882–1954)

René Le Senne, the French spiritualistic philosopher, was born in Elbeuf in Normandy. From 1903 to 1906 he was a pupil of Frédéric Rauh and Octave Hamelin at the École Normale Supérieure, where he passed the *agrégation* examination in philosophy in 1906. He obtained his doctorate in 1930 with a thesis titled *Le devoir* (Duty). After holding provincial teaching posts he was appointed to the Lycée Louis-le-Grand in Paris and, in 1942, to a chair of moral philosophy at the University of Paris. He distinguished himself as joint editor, with Louis Lavelle, of the series of works published in the collection “Philosophie

de l'esprit.” In 1948 he was elected to the Académie des Sciences Morales et Politiques.

The conception of philosophy underlying the “Philosophie de l'esprit” was traced by Le Senne to the Cartesian tradition, which, he held, identified existence with the act of thought and regarded existence as dependent upon a transcendent and infinite being. This tradition, according to Le Senne, was threatened both by positivism, which discounts the self-creating principle that raises man above causally determined physical nature, and by an excessive modern subjectivism, which makes man the measure of all things. Against these threats to the French “psycho-metaphysical” tradition Le Senne and Lavelle launched their series, in what they conceived as a kind of philosophicomoral mission, a reassertion of metaphysical philosophy against antiphilosophy.

Like much of recent French thought, Le Senne’s work evokes not so much René Descartes as Maine de Biran. The essence of the self is consciousness of action against the resistance and limitation of reality. This could be rendered: I will, or I strive, therefore I am. Thus, personality for Le Senne was “existence as it is formed by the double cogito: hindered by obstacles, elevating itself by and towards value.” Man participates in absolute and transcendent value. Although value outruns him and is not wholly his creation, it is made determinate by him in a given, concrete situation.

Reality, then, is at once the organ of self-creation and an obstacle to it. In a sense it degrades value, yet it actualizes value by making it determinate. We are, moreover, called back to awareness of the value-creating source in which we participate. This is a spiritual flow, or upsurge (*essor*). “Some obstacle has to break the continuity of the upsurge before the self, concentrating upon it the body’s energy, begins to will.” The willing self owes its being and consciousness to the obstacles it encounters. We participate in a world of absolute value and a world of brute reality and create ourselves unceasingly through them.

## LEŚNIEWSKI, STANISŁAW (1886–1939)

Leśniewski, Stanisław (1886–1939) was one of the founders of the Warsaw School of logic, which flourished from 1919 to 1939. He was the author of a highly original system for the foundations of mathematics, and one of the most innovative and unorthodox logicians of the twentieth century.

### LIFE AND INFLUENCE

Leśniewski was born in Serpukhov, Russia, and received his schooling in Irkutsk. After studying at German universities, including Leipzig and Munich, he moved in 1910 to Lwów where he studied philosophy with Kazimierz Twardowski and obtained his doctorate in 1912. Leśniewski published several papers before the First World War, which he spent in Moscow. His preoccupation with the logical antinomies, which began in 1911 when he read Jan Łukasiewicz's book *On the Principle of Contradiction in Aristotle*, shifted his interests permanently from philosophy of language to the logical foundations of mathematics. In 1919 he was appointed professor of the Philosophy of Mathematics at the University of Warsaw. From then until his early death from cancer he was at the center of developments in mathematical logic in Poland, first developing his systems, then from 1927 publishing his results. Leśniewski's notes, correspondence, and a monograph on the antinomies were destroyed in the 1944 Warsaw Uprising: After the war several of his surviving students worked to reconstruct the lost results.

Leśniewski's sole doctoral student Alfred Tarski—Leśniewski boasted proudly of having one hundred per-

cent geniuses as doctoral students—inherited many of his teacher's attitudes, but Tarski's increasing willingness to embrace platonistic set theory for the sake of metamathematical results caused tensions between them. Other pupils such as Jerzy Śłupecki, Bolesław Sobociński, Czesław Lejewski, and Henry Hiż remained closer to Leśniewski's views, but their influence was limited. Quine's concern with ontological commitment and the meaning of the quantifiers probably went back to discussions he had with Leśniewski in 1933 on the interpretation of higher-order quantification. Because of the inconvenience of his systems, his forbidding perfectionism, and the idiosyncrasy of his positions, Leśniewski's work remained outside the mainstream, but some aspects became widely influential outside Poland. These include: the object language/metalinguage distinction, exact canons of definition, the theory of semantic categories, and mereology.

### FORMAL SYSTEMS

After learning about Russell's Paradox, Leśniewski set himself to produce an antinomy-free foundation for mathematics. Disconcerted by the inexactitudes of Russell's and Whitehead's *Principia mathematica*, he initially forsook logical symbolism and formulated his views in highly regimented Polish, but in 1920 Leon Chwistek persuaded him to formalize his work, which he did with unprecedented precision. The logical order of Leśniewski's three systems is the reverse of the chronological order of their discovery. Leśniewski diagnosed an ambiguity in the notion of class which he made responsible for Russell's Antinomy, and in 1916 developed the theory of concrete classes, later renamed *mereology*. Then he set about formalizing the underlying logic of names, predicates and higher-order functors, which he called *ontology*, axiomatizing it in 1920. Finally he formalized the theory of sentences, connectives, and quantification which underlay the other theories, calling the resulting system *protothetic*. The axiomatization of protothetic was assisted by Tarski's 1923 discovery that conjunction could be defined in terms of material equivalence and universal quantification. Leśniewski and others improved the results through the 1920s, and he published accounts of protothetic in a series of German papers, and mereology in a Polish series.

### MEREOLGY

Mereology (from Greek *meros*, part), a formal theory of the part-whole relation and cognate concepts, is Leśniewski's nominalistically acceptable partial substitute

for set theory. It understands classes as concrete wholes literally composed of their members. Classes (now usually called mereological sums or fusions) are identical when they have the same parts, so the same sum may be determined by different pluralities of members—for example a chess board is the sum of its squares, but also of its ranks or its files. Sums exist if their members do, and a sum need not be spatiotemporally connected. There is no null or empty sum. Mereology can be axiomatized in many ways using many different undefined constants, its axiom(s) being added to ontology. The following perspicuous four-axiom system uses the primitive notion  $\text{pt}()$ , meaning *part of*, and understood to include the case of identity or improper part; the variables in this system are all nominal (intended singular variables being capitalized), and the ontological notion presupposed is the copula “ $\epsilon$ ” of singular inclusion:

- M1**  $\forall AB [ A \epsilon \text{pt}(B) \rightarrow B \epsilon B ]$   
**M2**  $\forall ABC [ ((A \epsilon \text{pt}(B) \ \& \ B \epsilon \text{pt}(C)) \rightarrow A \epsilon \text{pt}(C)) ]$   
**M3**  $\forall Ab [ A \epsilon \text{Sm}(b) \leftrightarrow (A \epsilon A \ \& \ \forall C [ C \epsilon b \rightarrow C \epsilon \text{pt}(A) ]$   
 $\ \&$   
 $\forall D [ D \epsilon \text{pt}(A) \rightarrow \exists EF [ E \epsilon b \ \& \ F \epsilon \text{pt}(E) \ \& \ F \epsilon \text{pt}(D) ] ] ) ]$   
**M4**  $\forall Ab [ A \epsilon b \rightarrow \text{Sm}(b) \epsilon \text{Sm}(b) ]$

These axioms say: (M1) that whatever has a part is an individual; (M2) that parthood is transitive; (M3) define the sum of all the  $bs$  as that unique individual  $A$  which overlaps all and only  $bs$ ; and state (M4) that if there is at least one  $b$  then the sum of all  $bs$  exists and is unique. Mereology is consistent relative to protothetic. It is independent of this system whether or not there are atoms—that is, objects without proper parts.

Mereology was the first system rigorously formulated by Leśniewski and remains the most thoroughly investigated. Its principles are much weaker than those of set theory, although some of its assumptions, especially the general sum principle M4, have been questioned on philosophical grounds. Especially when based on standard predicate logic rather than Leśniewski’s ontology, mereology has come into standard use in ontology and cognitive science.

## ONTOLOGY

Mereology presupposes ontology, so called because Leśniewski took it to formulate several meanings of *be*. He intended it as a modernized term logic of the sort formulated by Ernst Schröder, and in its admittance of empty and plural terms it is closer to traditional logic than to Frege–Russell predicate logic, whose terms are all

singular. Like mereology, ontology can be based on many different primitives, but the most frequently used is the one chosen by Leśniewski, namely the singular inclusion functor “ $\epsilon$ .” The basic sentence-form “ $A \epsilon b$ ,” readable as “ $A$  is a  $b$ ” but best read perhaps as “ $A$  is one of the  $bs$ ” captures the distributive rather than collective sense of “class”: “ $A$  is a member of the class of the  $bs$ ” just means “ $A$  is one of the  $bs$ ” and no individual called “the class of the  $bs$ ” is assumed.

Leśniewski’s original (1920) axiom, though not the shortest, remains the most perspicuous:

$$\text{O1 } \forall Ab [ A \epsilon b \leftrightarrow ( \exists C [ C \epsilon A ] \ \& \ \forall DE [ ( D \epsilon A \ \& \ E \epsilon A ) \rightarrow D \epsilon E ] \ \& \ \forall F [ F \epsilon A \rightarrow F \epsilon b ] ) ]$$

This says that  $A$  is a  $b$  if and only if (1) there is at least one  $A$ , and (2) there is at most one  $A$ , and (3) every  $A$  is a  $b$ . This axiomatic equivalence, which constitutes a sort of implicit self-definition of “ $\epsilon$ ” mirrors the analysis of singular definite descriptions by Russell, as can be seen by reading “ $A \epsilon b$ ” as “the  $A$  is a  $b$ .” Existential import in ontology is located in the functor “ $\epsilon$ ” rather than the quantifiers: “ $A \epsilon b$ ” is only true if an  $A$  exists.

The axiom is not ontology’s only source of logical power. Leśniewski allows new constants to be defined, and as these are introduced, new semantic categories of expression and thereby new categories of bindable variable become available. Each category of expression is subject to a principle of extensionality, and so the system grows in logical strength, ascending as required to higher types of variable. Thus although the axiom binds only nominal variables, later theses allow variables for predicates and other higher-order functors to be bound. Because Leśniewski allows plural names, his first-order calculus is equivalent in logical strength to standard monadic second-order predicate calculus. There is no axiom of choice in ontology, but a directive can be formulated allowing choice principles to be stated for each higher logical type (semantic category). Like mereology, ontology is consistent relative to protothetic. Despite its expressive power, ontology is ontologically neutral in that no thesis stating the existence of an individual can be derived. It is thus true of the empty universe as well as others.

Ontology is in many ways Leśniewski’s most innovative system, combining features of traditional, Schröderian, and Fregean logic with a potential expressive power

equivalent to that of the simple theory of types. Nevertheless, apart from some exploitation for purposes of historical comparison, and some development by Lejewski and others, it has found few supporters.

## PROTOTHETIC

The basis of Leśniewski's logic is protothetic, a bivalent propositional calculus to which may be added propositional functors of any order, and incorporating the theory of quantification. It is equivalent in potential to a system of propositional types. Leśniewski, following Peirce, took quantification as embodying cardinally unconstrained conjunction and disjunction, and as part of the basis of logic rather than attaching primarily to nominal variables. The quantifiers  $\forall$  and  $\exists$  bind variables of any category. Leśniewski experimented from 1921 onwards with different axiomatic and combinatorial bases for protothetic. He chose material equivalence as sole undefined connective because he formulated definitions as object-language equivalences, and he developed the calculus of equivalent statements. But an intuitive axiomatization of protothetic using implication is:

$$P1 \quad \forall pq [ p \rightarrow (q \rightarrow p) ]$$

$$P2 \quad \forall pqr [ f(r p) \rightarrow (f(r \forall s[s]) \rightarrow f(r q)) ]$$

Quantifier apart, the first thesis is familiar from propositional calculus. The second exploits a variable  $f$  for functors taking two propositional arguments, with " $\forall s[s]$ " a standard false sentence. Like ontology, protothetic derives much of its strength from the rules permitting the formulation of new definitions and extensionality principles for higher types. Each propositional type is finite in its extensions, starting from the basic types of sentences, which has just two extensions, the True and the False, so in principle the quantifiers can be replaced by computational principles running through the extensions for each type considered in a sentence. Leśniewski took great pains over protothetic but it remains the least discussed of his logical systems.

Though his published works covered mainly his own systems, with incidental but incisive criticism of such contemporaries as Russell and Whitehead, von Neumann and Zermelo, in his Warsaw lectures Leśniewski ranged more widely, finding single axioms for general and abelian group theory, developing Peano's axioms, investigating inductive definitions, comparing mereology with Whitehead's theory of events, and criticizing Łukasiewicz's many-valued logic.

## PHILOSOPHICAL METALOGIC

Though an unprecedentedly exact formalizer, Leśniewski deplored all formalism. Having come to logic through regimented ordinary language, he understood his logical systems throughout as interpreted with a determinate intended meaning, and intended his theses as general truths. From his first paper Leśniewski scrupulously distinguished use from mention of expressions, and literally failed to understand writings where this distinction was not observed, notably *Principia*. By contrast he admired and extolled the great rigor of Frege's formal systems, notwithstanding their inconsistency. Leśniewski's strictures on quotation were inherited and made influential by Tarski.

Leśniewski criticized Twardowski's platonism and strove to make his logical systems compatible with nominalism. This meant treating systems not as abstract entities but as concrete collections of physical inscriptions, growing in time by the addition of new inscriptions called *theses*. Because the systems as they develop allow new expressions to be introduced via definitions, and new types of variable to become available for quantification, the regulation of their growth had to be precise but schematic. Leśniewski achieved this by formulating for each system regulatory directives allowing new theses to be introduced. These directives are self-adjusting in that what they allow expands as the system grows. Leśniewski considered faulty definition to be responsible for the logical antinomies, and by bringing definitions within the system as object-language equivalences—rather than metalinguistic abbreviations—kept them under tight control. The highly complex directives for adding definitions in protothetic and ontology are Leśniewski's proudest achievement. To formulate them and the other directives governing substitution, quantifier distribution, modus ponens, and extensionality required a sequence of more than fifty metalogical definitions called *terminological explanations*. In his everyday logical working however, Leśniewski used an unofficial system of natural deduction from assumptions, understood as delivering an outline which could, if necessary be transformed into a proof according to the directives. This he never formalized. The complexities of formulating general terminological explanations and directives for variable-binding operators were beyond even Leśniewski, and he had to rest content in his official system with a sole syncategorematic operator, the universal quantifier.

The formulation of the directives employed Leśniewski's notion of semantic categories, a systematic logical grammar inspired by Frege's practice and

Husserl's theory of *Bedeutungskategorien*, and intended as an ontologically parsimonious alternative to type theory. Though not codified by Leśniewski, the subsequent systematization by Ajdukiewicz and others has made this part of mainstream logic and linguistics. The basic category of protothetic was the sentence, to which ontology added the basic category of name. Mereology required no new categories or directives.

Leśniewski had definite ideas about the intellectual economy of logic. A system ought to have as few primitive notions, axioms, and directives as possible; the axioms ought to be as short as possible, logically independent, and organic—that is, not contain provable theses as subformulas. The search for ever shorter axioms was a general feature of the Warsaw School, which Leśniewski and his followers sometimes pursued at the expense of defending controversial aspects of the systems, such as their interpretation of quantification, their radical nominalism, and their thoroughgoing extensionalism.

Leśniewski's avowed metaphysical neutrality combined with his liberal use of quantifiers to bind non-nominal variables drew criticism from Quine. Leśniewski rejected Quine's accusation of platonism, and on reflection Quine came to regard Leśniewski's quantifiers as substitutional, committing not to corresponding entities, but to expressions to be substituted for variables bound by a quantifier. That Leśniewski cannot understand the quantifiers objectually is clear because a standard empty name " $\wedge$ " can be substituted normally for bound variables: From the true "no  $\wedge$  exists" one may validly infer "for some  $a$ , no  $a$  exists," so "for some" ( $\exists$ ) cannot mean "there exists." In the light of its subsequent development, the substitutional interpretation fits Leśniewski no better than the objectual, because it would commit him to an infinity of platonic expression types. Comparison with standard accounts is complicated by Leśniewski's incriptional understanding of expressions and the import of his directives, which are conditional prescriptions rather than categorical descriptions. The directive "If  $A$  is the last thesis belonging to the system then a thesis  $B$  may be added if for some thesis  $C$  preceding  $A$ ,  $B$  is a result of substitution from  $C$  into  $A$ " quantifies only over extant tokens. The question remains how expressions employed in a logical system (including the quantifiers) have their meanings. On this Leśniewski remains silent. How to theorize metalogically about meaning and truth within Leśniewski's strictures remains perhaps the biggest open question concerning his systems.

## Bibliography

### WORKS BY LEŚNIEWSKI

The only collected edition of Leśniewski's works is their English translation:

Leśniewski, Stanisław. *Collected Works*. 2 vols., edited by Stanisław J. Surma, Jan T. J. Szrednicki, and Dene I. Barnett, with an annotated bibliography by V. Frederick Rickey. Dordrecht, Netherlands: Kluwer, 1992. Rickey's bibliography lists the original Polish locations of these writings.

Szrednicki, Jan T. J., and Stachniak, Zbigniew, eds. S. *Leśniewski's Lecture Notes in Logic*. Dordrecht, Netherlands: Kluwer, 1988. Contains edited transcriptions of student notes from lecture courses Leśniewski gave in Warsaw.

### WORKS ABOUT LEŚNIEWSKI

Luschei, Eugene C. *The Logical Systems of Leśniewski*.

Amsterdam, Netherlands: North-Holland, 1962. The most comprehensive monograph on Leśniewski.

Miéville, Denis. *Un développement des systèmes logiques de Stanislaw Lesniewski: Protothétique – Ontologie – Méréologie*. Berne, Switzerland: Lang, 1984. The nearest thing to an elementary introduction to Leśniewski.

Miéville, Denis and Denis Vernant, eds. *Stanislaw Lesniewski Aujourd'hui*. Grenoble, France: Université Pierre Mendès France, 1995. A collection of essays including an informative survey by Czesław Lejewski, "Remembering Stanislaw Lesniewski," pp. 25–66.

Szrednicki, Jan T. J., V. Frederick Rickey, and J. Czelakowski, eds. *Leśniewski's Systems: Ontology and Mereology*. Dordrecht, Netherlands: Kluwer 1984. Seminal commentaries and improvements by Lejewski, Słupecki, Robert E. Clay and others.

Szrednicki, Jan T. J., and Zbigniew Stachniak, eds. *Leśniewski's Systems: Protothetic*. Dordrecht, Netherlands: Kluwer, 1998. A similar compilation of important commentaries and improvements in protothetic.

Woleński, Jan. *Logic and Philosophy in the Lvov-Warsaw School*. Dordrecht, Netherlands: Kluwer, 1989. Definitive history, with a copious bibliography, situating Leśniewski in the context of the logical movement in Poland.

## LESSING, GOTTHOLD EPHRAIM (1729–1781)

Gotthold Ephraim Lessing, the German dramatist and critic, was born at Kamenz in Saxony. The son of a scholarly Lutheran pastor, he was sent to study theology at Leipzig University. There, however, he absorbed the popular rationalism of the Enlightenment, whose leading

contemporary exponent was the Leibnizian Christian Wolff, of Halle. Lessing was influenced in the same direction by his friends from Berlin, Christoph Friedrich Nicolai and Moses Mendelssohn, and by the writings of the English deists, many of which had been translated into German. Although literature, and especially the drama, became Lessing's supreme interest, he was to return to theology in the last decade of his life. He has no special claim to being ranked as a philosopher of originality and distinction, but with regard to the diffusion of certain ideas and attitudes among educated minds, his historical influence is preeminent. He was above all a critic, and his attitude may be described as one of "passionate detachment." His nonconformity made him appear to be perennially restless; he was never permanently satisfied to adopt the conventional opinions of society, always preferring to be in a "minority of one." The movement of his mind carried him beyond his parents' theological beliefs and the commonplace deism of his twenties until, through his invocation of Benedict de Spinoza, he eventually prepared the way for the romantic reaction against the Enlightenment.

#### LITERATURE AND ART

Lessing's approach to the drama was based on his conviction that it was urgently necessary to break the tyrannical dominance over German literature exerted by the established French classicism—a trend that was encouraged by Frederick II of Prussia. In Lessing's eyes, the effect of this French influence was the suppression of the native German genius. In a series of "literary letters" (*Briefe, die neueste Literatur betreffend*, Leipzig, 1759–1765), written in cooperation with Nicolai and Mendelssohn, Lessing exhorted German writers to turn their backs on the artificial perfections of Pierre Corneille and Jean Racine; he claimed that they should take as their stylistic model the bold naturalism of William Shakespeare, whom Voltaire had characteristically dismissed as a "drunken savage."

Lessing's best-known work of criticism is his *Laokoon, oder, über die Grenzen der Malerei und Poesie* (*Laocoön, or the Bounds of Painting and Poesie*, Berlin, 1766). Judged as constructive thinking about the nature of art, it is a disappointing work, although it is noteworthy in that it contains the first explicit statement of the concept of "art for art's sake." Moreover, its overt thesis—that painting works by forms and colors in space, while poetry belongs to a quite different category in that it sets out to describe successive moments in time—is not only inadequate, since it fails to take account of lyric poetry and indeed of all poetry that describes states of mind, but

also much less original than Lessing implied. But it is significant that the *Laokoon* takes the form of a critique of Lessing's German, English, and French predecessors; he could not write well without a target to attack. In the *Laokoon*, Lessing's main critique was directed against Johann Joachim Winckelmann and the latter's idealization of "noble simplicity and quiet grandeur." Lessing was prepared to acknowledge that this ideal may hold good for painting, which, he claimed, is exclusively concerned with the beauty of physical form. But he wholly denied its validity or relevance for judging poetry, which is concerned with action and passion. *Laokoon*, like much that Lessing wrote, has a subtle undercurrent of irony and polemic, the thrust of which, on the surface, is not apparent to the rapid reader. Although Lessing took as his text a famous piece of ancient sculpture, his essay is more an oblique sermon about literature than an aesthetic analysis of the visual arts by a critic with a real understanding of, or even sympathy for, his subject. Its essential thesis is a warning that Winckelmann's neoclassical ideals must not constrict the freedom of the poet, who, unlike the painter, is primarily concerned with passionate action.

Lessing's writings on art and literature do not constitute a serious analysis and critique of aesthetic experience. But his work was directed toward liberating the artist from all the limiting rules and conventions of artificial formality. Lessing was not in any sense a romantic writer, but because of his demand for the free expression of natural feelings and his retrospective interest in antiquity, he occupies an important place among the forces that made German romanticism possible. The significance of Lessing's role as a precursor of the romantic movement emerges even more prominently in his treatment of religious problems. He initiated the endeavor to discover within the immanent order of the world those values that had been derived by traditional Christianity from a transcendental view of the universe.

#### HISTORY AND THEOLOGY

Lessing inherited from his father strong scholarly and historical interests. By temperament antipathetic to all partisan historiography, he published a series of *Rettungen* (Vindications) in 1754, in which he defended historical figures to whom ecclesiastical historians, for dogmatic reasons, had not been quite fair. These essays are quite characteristic of Lessing's nature and cast of mind. Written with suppressed passion and permeated with a profound sense of engagement, they nevertheless remain uncommitted to any personal judgment either for or against the doctrinal beliefs of those whom he was vindicating.

cating. His neutrality toward Christianity never took the form of quasi-Gibbonian irony. He always wrote as one wholly sympathetic to Christian ethical ideals, but coolly reserved toward dogmatic formulas that breed unreasoning prejudice and the negation of humane values.

The turning point of Lessing's life occurred in 1769, when he became librarian for the duke of Brunswick at Wolfenbüttel. In 1773 he began to publish essays on historical theology based on the Wolfenbüttel manuscripts. Earlier, during a three-year residence in Hamburg from 1766 to 1769 as a theater critic, Lessing had met the deist Hermann Samuel Reimarus (1694–1768), whose daughter had lent him the manuscript of an unpublished book by her father titled *Apologie oder Schutzschrift für die vernünftigen Verehrer Gottes* (Apology for rational worshipers of God). In 1774, and from 1777 to 1778, Lessing printed extracts from this work as fragments from the writings of an anonymous and unidentifiable deist whose manuscripts had presumably been found in the Wolfenbüttel library (“Wolfenbüttler Fragmente eines Ungenannten,” in *Beiträge zur Geschichte und Literatur*).

The last and most important fragment precipitated a violent controversy with a Hamburg pastor, Johann Melchior Goeze, and effectively initiated the long nineteenth-century quest for the Jesus of history behind the Christ of faith. Reimarus was a believer in natural religion, but he was skeptical about revelation. His objections to traditional Christianity presuppose that biblical inerrancy is essential to faith. Lessing sometimes wrote as if he shared this assumption and sometimes as if he did not, so that it is not possible to arrive at a strictly coherent view on this point.

In his more cynical moments, Lessing treated liberal theology, such as that represented by J. S. Semler of Halle, with hostile contempt, on the ground that it was deceptively credible; he preferred to “defend” orthodoxy as being so patently absurd that by defense it would be sooner ended. Strictly as a scholar, Lessing was Semler's inferior; nevertheless, Lessing's genuinely scholarly instinct, combined with his inner detachment from the entrenched positions of the contemporary theological schools, as well as from those of the Enlightenment, enabled him to begin the critical study of the sources of the Synoptic Gospels (a fundamental question on which Reimarus had naively said nothing) with his pioneer essay, *Neue Hypothese über die Evangelisten als bloss menschliche Geschichtsschreiber betrachtet* (New Hypothesis concerning the Evangelists Regarded as Merely Human Historian). This was written from 1777 to 1778 and first printed in 1784 in Lessing's *Theologische Nachlass*.

Prevented by the duke of Brunswick from indulging in theological controversies, Lessing put his theology into a play, *Nathan der Weise* (*Nathan the Wise*, 1779) which was a plea for religious indifferentism on the ground that what is required of man is not an assent to the propositions of a creed, but sincerity, brotherly love, and tolerance. It is not easy to discover precisely what Lessing's positive beliefs were, so little did he commit himself, either in published writings or even in private correspondence, to any positive avowal of convictions. But he certainly accepted the commonplace thesis of the Enlightenment that the quintessence of Christianity, hidden beneath the accretions of theology, consists in universal brotherhood and a basic moral code. Like many rationalists of his age, he passed for a time into Freemasonry, though he emerged disillusioned with what was for him evidently a pale substitute for Christianity. In one sense, it could be said that Lessing spent his life hoping that Christianity was true and arguing that it was not. But his basic attitude toward religious belief was neither one of affirmation nor of denial; it took the form of an impassioned question.

Lessing was the first modern writer explicitly to emphasize that even if conclusions about historical events were more certain than they are, any religious affirmation based upon them involves a transition to another plane of discourse, that of faith. He was torn between the idea of revelation as the communication of timeless propositional truths, and the untidiness and irrationality of history. “Accidental truths of history can never become the proof of necessary truths of reason” (*Über den Beweis des Geistes und der Kraft*, 1777). Events and truths belong to altogether different categories, and there is no logical connection between one and another. Lessing's statement of this antithesis presupposes on the one hand the epistemology of Gottfried Wilhelm Leibniz, with its sharp distinction between necessary truths of reason (mathematically certain and known a priori) and contingent truths (known by sense perception), and on the other hand the thesis of Spinoza's *Tractatus Theologico-Politicus*, that the truth of a historical narrative, however certain, cannot give us the knowledge of God, which should be derived from general ideas that are in themselves certain and known. Lessing's own way out of the dilemma was to conceive the role of religious belief in the historical process as a relative state in the advance of humanity toward maturity, a thesis that he argued at length in the tract *Die Erziehung des Menschengeschlechts* (The Education of the Human Race; Berlin, 1780). Lessing thus became the father both of the “post-Christian” consciousness expressed in nineteenth-century posi-

tivism, and of the liberal religion of thinkers such as Samuel Taylor Coleridge and Frederick Denison Maurice.

There is more relativism than skepticism in Lessing's view. He did not think that absolute truth is revealed; but even if it were, and even if he were capable of apprehending it, he would not have wished to apprehend it. Adapting an aphorism of Clement of Alexandria, Lessing declared:

The worth of a man does not consist in the truth he possesses, or thinks he possesses, but in the pains he has taken to attain that truth. For his powers are extended not through possession but through the search for truth. In this alone his ever-growing perfection consists. Possession makes him lazy, indolent, and proud. If God held all truth in his right hand and in his left the everlasting striving after truth, so that I should always and everlastingly be mistaken and said to me, Choose, with humility I would pick on the left hand and say, Father grant me that; absolute truth is for thee alone. (*Eine Duplik*, K. Lachmann and F. Muncker, eds., Vol. XIII, p. 23)

### THE MOVE TO IMMANENTISM

Several fragmentary notes found among Lessing's papers, and published in 1784 by his brother Karl in *Theologischen Nachlass*, disclose the extent of Leibniz's influence. Lessing's interest was always most deeply aroused by Leibniz's references to theology and ethics. One of these pieces, written by Lessing about 1753, "Das Christentum der Vernunft" (The Christianity of Reason), foreshadowed a section of *Die Erziehung* in its attempt at making a speculative restatement of the doctrine of the Trinity, with the help of Leibnizian ideas on the hierarchy of being and the harmony of the monads. But there is a strong admixture of Spinoza in Lessing's conception of this harmony; he did not think of it as something preestablished by a Creator who is a superobject behind and beyond phenomena, but rather as being itself God, so that the perfect continuum of existents, in which there can be no gap, is indistinguishable from the perfection of the divine being. Similarly, in the brief notes titled "Ueber die Wirklichkeit der Dinge ausser Gott" (On the Reality of Things outside God; written in 1763, published in 1795 in Karl Lessing's *Lessings Leben*), Lessing denied the thesis of traditional theism that the created world exists independently of its Creator, in the sense of being distinct from him. Lessing urged that nothing can be outside the divine mind, and that there need be no hesitation before the conclusion that, since ideas of contingent things are

themselves contingent, there is contingency even in God. These aphoristic fragments hardly amount to a coherent system. They show Lessing looking toward Spinoza, whom he had studied in his years at Breslau from 1760 to 1765, for a solution to some of the problems left unanswered by Leibniz.

Leibniz had formally asserted the freedom of the will, though it was doubted by Pierre Bayle and others whether Leibniz's libertarian assertions were in fact fully compatible with his philosophical principles. Lessing agreed with Spinoza that free will is a superfluity and an illusion. In 1776 Lessing published the *Philosophische Aufsätze* ("Philosophical Papers") of Karl Wilhelm Jerusalem, with the intention of making a protest against Johann Wolfgang von Goethe's *Werther*, with its description of Jerusalem's suicide. In a note to Jerusalem's third essay Lessing commented on his wisdom in recognizing that freedom is nothing but a cause of anxiety and fear, and that the recognition of necessity and destiny as beneficent is the only way to true happiness. "I thank my God," Lessing added, "that I am under necessity, that the best must be." The notion that the moralist has anything to fear from deterministic philosophies is just a mistake.

In 1785 at Breslau, Friedrich Heinrich Jacobi published his *Ueber die Lehre des Spinoza in Briefen an der Herrn Moses Mendelssohn* (Letters to Moses Mendelssohn on Spinoza's Doctrine), in which he disclosed that at Wolfenbüttel in July 1780, he had been told by Lessing, seven months before Lessing's death, that he could not believe the old transcendental metaphysic, and that he unreservedly accepted the pantheism of Spinoza—"There is no other philosophy." Jacobi was astonished to hear Lessing add that the determinism of Spinoza was no obstacle to him, and indeed that he had no desire for free will. Jacobi's revelations precipitated a furious controversy known as the *Pantheismusstreit*. The Enlightenment had derived from Bayle's *Dictionnaire historique et critique* such an unflattering picture of Spinoza that Jacobi's attribution of Spinozistic views to Lessing seemed like a shocking libel of a dead man. Moses Mendelssohn was moved to write an irate reply, in which he denied that Lessing was a pantheist and a determinist. Although not all of Jacobi's deductions were correct, the substantial accuracy of his account of what Lessing said is sufficiently vindicated by the fragments found among Lessing's papers. Lessing's final creed was a belief in an immanent destiny, with no room either for the concept of transcendence or for special revelation in any form; he believed in a determined pattern of cause and effect extending not

only throughout the physical order of nature, but also to morality and “the realm of ends.”

Lessing’s legacy to posterity was therefore to give an impetus to the notion of historical inevitability, especially in *Die Erziehung des Menschengeschlechts* at the end of which he even toyed with speculations about the transmigration of souls—obviously because this concept seemed to him more compatible with his historical determinism than the traditional eschatology connected with the Christian ideas of freedom and of personality.

The strong influence of Lessing is manifested in the history of religious thought in the nineteenth century. It can be traced particularly in the work of Søren Kierkegaard, whose *Concluding Unscientific Postscript* took its starting point from Lessing’s statement about the intellectually impossible leap from the contingent truths of history to the necessary truths of divine revelation. The other, more liberal, side of Lessing was reflected in Coleridge, whose work was even suspected of being a plagiarism of Lessing’s. In the field of literature and art, Lessing’s attack on French classicism opened the way for the romantic ideal of free self-expression and naturalism, while his final theological position of Spinozistic immanentism clearly foreshadowed Friedrich Daniel Ernst Schleiermacher’s *Speeches on Religion (Reden über die Religion, 1799)*. His consciousness of living in an age of humanist maturity anticipated the Hegelian and Comtian estimates of religion as a useful, though now surpassed, stage in the education of humanity toward something higher and truer. Probably Lessing did as much as anyone to encourage among the educated European minds of his time an attitude of critical doubt that would lead to passionate engagement, rather than impersonal remoteness.

## LEUCIPPUS AND DEMOCRITUS

Leucippus and Democritus were the earliest Greek atomists. The originator of the atomic theory, Leucippus (fifth century BCE), must be considered a speculative thinker of the first order, but to Democritus (c. 460–c. 370 BCE) must go the credit for working out the detailed application of the theory and supporting it with a subtle epistemology. Moreover, the range of Democritus’s researches surpassed that of any earlier philosopher, and he appears to have been an original and, for his day, advanced ethical thinker.

We have very little biographical data for Leucippus. Epicurus is even reported to have said that there was no

philosopher Leucippus, but the evidence of Aristotle decisively refutes this opinion (if, indeed, Epicurus did not merely intend to deny Leucippus's philosophical importance). Leucippus was probably born at Miletus; reports associating him with Elea or Abdera should be taken as reflecting views concerning his philosophical affiliations rather than as reliable evidence for his birthplace. He was presumably older than Democritus. His book *On Mind* may have been directed partly against Anaxagoras, and according to Theophrastus, Diogenes of Apollonia derived some of his theories from Leucippus. All this suggests that Leucippus was a slightly younger contemporary of Anaxagoras and that his main philosophical activity fell some time within the broad limits of 450–420 BCE.

Democritus was born at Abdera. He described himself in the *Little World-System* as a young man in the old age of Anaxagoras; Diogenes Laërtius says that he was forty years younger than Anaxagoras. On this evidence the date given for his birth by Apollodorus (in the 80th Olympiad, 460–456 BCE) is generally preferred to that suggested by Thrasyllus (the third year of the 77th Olympiad, 470–469 BCE). He is variously reported to have lived between 90 and 109 years. To judge from the number of his writings, his literary activity extended over a considerable period, but we have no means of assigning different works to different times in his life. His statement that he wrote the *Little World-System* 730 years after the fall of Troy (Diogenes Laërtius, *Lives* IX, 41) is of little value since we cannot tell which of several possible chronologies for the Trojan War Democritus accepted.

Many stories, most of them apocryphal, relating to Democritus's life and character circulated in antiquity. There are the accounts of his saving the Abderites from a plague, of his dying by voluntarily abstaining from food, and of his reputation as the "Laughing Philosopher." The tradition that he traveled extensively is, however, more plausible and better grounded. The authenticity of the fragment (299) in which he claimed to be the most widely traveled of his contemporaries is disputed, and the genuineness of the five books dealing with foreign travel mentioned by Diogenes Laërtius (for example, *A Voyage round the Ocean*) has also been doubted. But evidence concerning his travels goes back to Theophrastus (see Aelian, *Varia Historia* IV, 20), and the reports that he visited such places as Egypt, Chaldea, and the Red Sea (see Diogenes Laërtius, *Lives* IX, 35) may well have a sound basis in fact.

All that has been preserved of the original writings of Leucippus and Democritus is a poor selection of isolated

quotations, most of which derive from the ethical works of Democritus. For the atomic theory itself we rely on reports in Aristotle, Theophrastus, and later doxographers, who were often unsympathetic to the views of the atomists. In most of the principal texts referring to Leucippus, his doctrines are not clearly distinguished from those of Democritus, and the precise contribution of each philosopher is in question. Aristotle, however, undoubtedly treated Leucippus as the founder of atomism (*De Generatione et Corruptione* 325a23ff.), and we may reasonably attribute both the principles of the physical theory and a fairly complex cosmogony to him. Democritus evidently elaborated the atomic theory and was responsible for the detailed account of sensible qualities, besides going far beyond Leucippus both in the range of his scientific inquiries and in his interest in moral philosophy.

## WRITINGS

Only two works are ascribed to Leucippus, *On Mind*, from which our sole surviving quotation comes, and the *Great World-System*, which may be attributed to Leucippus on the authority of Theophrastus (Diogenes Laërtius, *Lives* IX, 46), although Thrasyllus later assigned it to Democritus.

Democritus, on the other hand, wrote some sixty-odd works, the titles of which provide valuable evidence of the scope of his interests. The main works were cataloged by Thrasyllus into thirteen tetralogies. Two tetralogies are devoted to ethics and four to physics (including *Little World-System*, *On the Planets*, *On Nature*, *On the Nature of Man*, *On the Senses*, and *On Colors*). These were followed by nine works not arranged in tetralogies—for example, *Causes of Celestial Phenomena*, *Causes concerning Seeds, Plants and Fruits*, and three books of *Causes concerning Animals*. Three tetralogies are classified as mathematics, two deal with music and literature, and two consist of technical works, including treatises on medicine, agriculture, painting, and warfare. Nine other miscellaneous works, mostly concerning travel, are also mentioned by Diogenes Laërtius but are less certainly authentic as they were not included in Thrasyllus's catalog.

Democritus's style is described by Cicero as elegant (*De Oratore* I, 11, 49) and lucid (*De Divinatione* II, 64, 133), and an anecdote recorded by Diogenes Laërtius (*Lives* IX, 40) implies that his works already had wide circulation by the time of Plato.

## THE ATOMIC THEORY

The basic postulate of Greek atomism in its original form was that atoms and the void alone are real. The differences between physical objects, including both qualitative differences and what we think of as differences in substance, were all explained in terms of modifications in the shape, arrangement, and position of the atoms. Aristotle illustrates these three modes of difference with the examples A and N, AN and NA, and  $\Xi$  and H.

This theory was already interpreted by Aristotle as an answer to the Eleatic denial of change and movement. Other post-Parmenidean philosophers had countered this denial in different ways, but both Empedocles and Anaxagoras had assumed a variety of elemental substances, on the one hand, the four “roots,” on the other, an original mixture containing every kind of natural substance. In postulating a single elemental substance, Leucippus remained closer to Parmenides’ own conception. In common with Parmenides’ One Being the individual atoms are ungenerated, indestructible, unalterable, homogeneous, solid, and indivisible. Leucippus may be said to have postulated an infinite plurality of Eleatic ones, and he may even have been directly influenced by Melissus’s argument (Fr. 8) that “if there were a plurality, they would have to be as the One is.” Leucippus also agreed with the Eleatics that without void movement is impossible. Yet whereas the Eleatics denied the existence of the void, or “what is not,” Leucippus maintained that not only “what is” (the atoms), but also “what is not” (the void), must be considered real. Leucippus thereby reinstated both plurality and change; the void is that which separates the atoms and that through which they move.

The atoms are infinite in number, dispersed through an infinite void. Their shapes are infinitely various, there being no reason that any atom should be of one shape rather than another. Democritus, at least, also allowed differences in the sizes of the atoms, but whether he thought any atom large enough to be visible seems doubtful. Late sources that report that atoms are unlimited in size as well as number (Diogenes Laërtius, *Lives* IX, 44) or which suggest the possibility of an atom the size of the world (Aëtius, *Placita* I, 12, 6) are difficult to credit in view of the testimony of Aristotle, who apparently believed that for both Leucippus and Democritus the atoms are all so small that they are invisible.

The atoms are in continuous motion. Aristotle, among others, objected that the atomists did not explain the origin of movement or say what kind of movement is natural to the atoms. However, they evidently assumed that the motion of the atoms is eternal, just as the atoms

themselves are, and they perhaps drew no clear distinction between original and derived motion. Although Epicurus was later to suggest that atoms naturally fall vertically, the earlier atomists probably did not consider movement in any particular direction prior to movement in any other. Weight for them, it seems, was not a primary property of the atoms nor a cause of their interactions, although in a developed cosmos the atoms have “weight” corresponding to their size (and the weight of compound bodies varies according to the proportion of atoms and void they contain).

The movements of the atoms give rise to constant collisions whose effects are twofold. Sometimes, the atoms rebound from one another; alternatively, when the colliding atoms are hooked or barbed or their shapes otherwise correspond, they cohere and thus form compound bodies. Change of all sorts is accordingly interpreted in terms of the combining and separating of atoms, which themselves remain unaltered in substance. The compound bodies thus formed possess various sensible qualities—color, taste, temperature, and so on—and Democritus undertook a detailed exposition relating these qualities to specific atomic configurations.

**COSMOGONY.** Evidence concerning Leucippus’s cosmogony comes mainly from Diogenes Laërtius (*Lives* IX, 31ff.). The process begins when a large group of atoms becomes isolated in a great void. There they conglomerate and form a whirl or vortex in which atoms of similar shape and size come together. In this vortex the finer atoms are squeezed out into the outer void, but the remainder tend toward the center, where they form a spherical mass. More atoms are drawn into this mass on contact with the whirl, and some of these are ignited by the speed of the revolution, thus forming the heavenly bodies. Earth is formed by atoms that cohere in the center of the mass. The cosmogonical process is not unique. The atomists argued that since atoms and the void are infinite, there are innumerable worlds. These worlds are not all alike, however; Democritus held that some worlds have no sun or moon and that some lack moisture and all forms of life (Hippolytus, *Refutatio* I, 13, 2f.).

Several features of this account are obscure, and two apparently conflicting criticisms were leveled against it in antiquity—first, that although the atomists asserted that the cosmogonical process came about by necessity, they did not explain what this necessity was (Diogenes Laërtius, *Lives* IX, 33); second, that they maintained that it occurred spontaneously (Aristotle clearly has the atom-

ists in mind when he considered this view, *Physics* 196a24ff.).

But Aristotle's judgment should be taken as referring primarily to the atomists' exclusion of final causes; in Aristotelian terms the atomists held that the world arose spontaneously because they denied that it was intelligently planned. Leucippus explicitly stated that "nothing happens at random, but everything for a reason and by necessity" (Fr. 2), and throughout their cosmology the atomists not only excluded purpose or design but also assumed that every event is the product of a definite, theoretically determinable cause. Thus, they doubtless conceived the vortex to arise from certain mechanical interactions between the colliding atoms, although it is unlikely that they attempted to say precisely how this came about. Democritus illustrated his doctrine that like things tend to come together with examples drawn from both the inanimate and the animate sphere (Fr. 164). And like many of the pre-Socratics, the atomists constructed their cosmogony in part on an embryological model. The outer envelope of the world was likened to a membrane, and in both Leucippus's cosmogony and Democritus's embryology the process of differentiation apparently takes place from the outside (see Aristotle, *De Generatione Animalium* 740a13ff.).

**ASTRONOMY AND BIOLOGY.** Leucippus's astronomical theories are surprisingly retrograde. He accepted the old Ionian picture of a flat earth, tilted toward the south, and he believed that the sun is the most distant of the heavenly bodies. Democritus's theories were generally less crude, and he attempted rational explanations of a wide variety of obscure phenomena. He accepted Leucippus's account of Earth with only minor modifications (Aëtius, *Placita* III, 10, 5) but corrected his notion of the relative positions of the heavenly bodies, observing, for example, that the planets are not equidistant from Earth and placing Venus between the sun and moon. Among other topics on which some of Democritus's theories are recorded are the behavior of the magnet, the nourishment of the embryo, and the relative longevity of different types of plants. Of his biological doctrines the notion that the seed is drawn from the whole of the body (the pangensis theory) was particularly influential (Aëtius, *Placita* V, 3, 6).

**SOUL, KNOWLEDGE, AND SENSATION.** Our evidence concerning the atomists' psychological and epistemological doctrines derives very largely from Democritus, although his theory of the soul was probably developed from ideas outlined by Leucippus. This theory was a

materialist one in line with the principles of atomism. Democritus conceived of the soul as consisting of spherical atoms, this being the shape best adapted to penetrate and move things. Fire, too, is composed of spherical atoms, and he evidently subscribed to the common Greek belief in the connection between life and heat, now interpreted in terms of the similarity in the shapes of soul atoms and fire atoms. The soul atoms tend to be extruded from the body by the pressure of the surrounding air, but this process is counteracted by other soul atoms that enter the body with the air we breathe; life depends on this continuous replenishment.

Our main source for Democritus's theory of knowledge is Sextus Empiricus. Several of the fragments that he quotes appear to express an extreme skepticism—for instance, "We know nothing truly about anything" (Fr. 7). However, Fragment 11 shows that Democritus was no outright skeptic. There he distinguished between two modes of cognition; the senses provide what is called a "bastard" knowledge but contrasted with this is a "legitimate" knowledge, which operates on objects too fine for the senses to perceive. Clearly, "legitimate" knowledge relates to atoms and the void, which alone are real; the objects of sensation, on the other hand, exist "by convention" (Fr. 9). The doctrine enunciated in the fragments is that sense perception is not trustworthy, and Aristotle's repeated statement that the atomists found truth in appearance (*De Generatione et Corruptione* 315b9ff.) should be understood as an interpretative comment based on Aristotle's own conception of the distinction between sensibles and intelligibles. Yet although we must rely on reasoning to attain knowledge, Democritus acknowledged that the mind derives its data from the senses (Fr. 125). Not a pure intellectualist like Parmenides, a crude sensationalist like Protagoras, nor a complete skeptic as Gorgias made himself out to be, Democritus advocated critical reflection on the evidence of the senses as our best means of approaching the truth; yet since thought itself, like sensation, involves physical interactions between atoms, it, too, is subject to distortion, and even "legitimate" knowledge is at best, it seems, only opinion (Fr. 7).

Democritus's detailed accounts of the five senses were reported and criticized at length by Theophrastus (*De Sensibus* 49–82). According to Alexander (*In Librum de Sensu* 24, 14ff.), Leucippus already held that physical objects constantly emit images that effect vision on entering the eye. Democritus modified and complicated this doctrine by suggesting that images from both the object and the eye itself meet and imprint the air in front of the

eye. Each of the other senses, too, is produced by contact between the organ and images deriving from the object, and thought was analogously explained as the contact between soul atoms and images coming from outside the body. But not content merely to assert in general terms that secondary qualities are due to differences in the shapes and sizes of the atoms, Democritus also proposed a detailed account relating specific tastes, colors, smells, and so on to specific shapes. Thus, an acid taste is composed of angular, small, thin atoms and a sweet taste of round, moderate-sized ones. Democritus's primary colors—black, white, red, and greenish yellow—were similarly associated with certain shapes and arrangements of atoms, and other colors were derived from combinations of these four. For all its crudities Democritus's theory may claim to be the first fully elaborated account of the physical basis of sensation.

**MATHEMATICS.** Democritus's interest in mathematics is apparent from the titles of five works dealing with mathematical subjects, and we are told, for example, that he discovered the relation between the volumes of a pyramid and a prism with the same base and equal height. We have, however, little evidence on the part of his mathematical work that related directly to the atomic theory. The atoms are definitely conceived of as physically indivisible (on the grounds that they are solid and contain no void), but it is not clear whether they are absolute minima in the sense of being mathematically indivisible. Epicurus later distinguished between atomic bodies (which are physically indivisible but logically divisible) and the "minima in the atom." But Aristotle appears to have assumed that Leucippus and Democritus themselves drew no distinction between the limits of physical and mathematical divisibility (*De Generatione et Corruptione* 315b28ff.), and he considered that their atomic theory necessarily conflicted with the mathematical sciences (*De Caelo* 303a20ff.). Unless Aristotle has completely misrepresented the atomists, it would appear that Democritus was unaware of any inconsistency in holding both (1) that the atoms have different shapes and sizes and (2) that they are mathematically as well as physically indivisible. But it must be repeated that the evidence on which to convict or absolve Democritus of this gross confusion is scanty.

**ETHICS.** Although serious doubts have been raised concerning the transmission of the ethical fragments of Democritus, most scholars now consider that the majority of those accepted by Hermann Diels and Walther Kranz may be used as a basis from which to reconstruct

his ethics. There remain, however, wide disagreements on the nature and value of his moral teaching. Alongside the fragments that convey traditional sentiments (for example, on the dangers of fame and wealth if not accompanied by intelligence) we find others that expound notions far in advance of the popular morality of the day, as, for instance, the doctrine that it is one's own consciousness of right and wrong, not fear of the law or public opinion, that should prevent one from doing anything shameful (Frs. 181, 264). And sayings such as Fragment 45 ("The wrongdoer is more unfortunate than he who is wronged") express views more commonly associated with Socrates than with Democritus.

The ethical ideal is termed "well-being" or "cheerfulness," which is to be gained through uprightness and a harmonious life. Although Democritus clearly implied that life without pleasure is not worth living and even said that pleasure is the mark of what is expedient (Fr. 188), it is the higher pleasures of the soul that we should cultivate, not those of the body. Sensual pleasures are condemned as short-lived. He repeatedly stressed that we should moderate our desires and ambitions, become self-sufficient, and be content, in the main, with simple pleasures. Yet Democritus was no quietist. Rather, he recognized that worthwhile objects are to be achieved only through effort (Frs. 157, 182).

One of the salient features of Democritus's ethics is his rejection of supernatural sanctions of behavior. In part, he seems to have rationalized belief in the gods as a mistaken inference from terrifying natural phenomena (Sextus, *Adversus Mathematicos* IX, 24), and yet he did not dismiss notions of the gods entirely, for he appears to have related certain such ideas to images, some beneficent, some harmful, that visit humans (Fr. 166). Religious sanctions are, however, rigorously excluded from his ethics. He refuted those who concocted fictions concerning the afterlife (Fr. 297), and he spoke with apparent irony of those who prayed to Zeus as "king of all" (Fr. 30). Equally, he castigated those who invented chance as an excuse for their own thoughtlessness or who failed to recognize that their misfortunes stemmed from their own incontinence (Frs. 119, 234). Throughout his ethics he may be said to have set high standards of personal integrity and social responsibility.

The question of the relation between Democritus's ethics and his physics has been much debated. In some respects, such as in the idea that excesses "cause great movements in the soul"—that is, presumably, in the soul atoms (Fr. 191)—his ethics reflect a psychology that is based on his physical theories. Whether we should expect

other aspects of the atomic doctrine to be in evidence in the ethical fragments seems very doubtful. Democritus clearly did not feel (nor need he have felt) that the notion of necessity in his physics (the belief that every event has a definite cause to be sought in the interactions of the atoms) conflicted with his doctrine of moral responsibility in the sphere of human behavior. His denial of supernatural sanctions in his ethics parallels his rejection of teleology in his cosmology. And his ethics have in common with his epistemological theory that he argued against an unreflecting acceptance of the evidence of the senses concerning what is pleasant just as much as concerning the nature of reality as a whole.

**SOCIOLOGY AND POLITICS.** The only indication we have of Democritus's political leanings is the idealistic but otherwise rather inconclusive Fragment 251: "Poverty under democracy is as much to be preferred to so-called happiness under tyrants as freedom to slavery." It has, however, been conjectured that the account of the origin of civilization preserved in Diodorus (*Bibliotheca Historica* I, 8) owes much to Democritus. According to this, primitive peoples originally gathered in groups for the sake of mutual protection from wild animals, and subsequently language and the arts were also invented under the spur of human needs. It is very uncertain how far this reproduces Democritus's ideas, but there is some evidence in the fragments that he maintained a naturalistic theory of civilization and progress and excluded teleological explanations here, as he did elsewhere in his philosophy. Fragment 144 may be taken to suggest that he believed that the earliest arts (although not some of the later ones) were products of necessity, and in Fragment 154 he argued that humans learned many of their skills by copying the behavior of animals.

The theory founded by Leucippus and developed by Democritus was the most coherent and economical physical system of its day, and the history of its influence can be traced from the fourth century BCE to modern times. Although Plato mentioned neither Leucippus nor Democritus, the *Timaeus* is markedly indebted to their thought. Even Aristotle, who rejected atomism outright, conceded that of all his predecessors Democritus was the most notable physicist. Later, the Epicureans championed atomism against the continuum theory of the Stoics. Leucippus's theory, in origin primarily an answer to the Eleatic arguments against change, was the first clear formulation of the doctrine that matter exists in the form of discrete particles, and as such it may legitimately be considered the prototype of modern theories of the discontinuous structure of matter, even though the nature of

such theories, the problems they are intended to resolve, and the methods used to establish them all differ fundamentally from those of ancient atomism.

### **Bibliography**

The extant fragments of Leucippus and Democritus and the principal reports and commentaries in ancient authors are collected in Hermann Diels's *Die Fragmente der Vorsokratiker*, Vol. II, 6th ed., with additions by Walther Kranz, ed. (Berlin, 1952). There is an English translation of the fragments in Kathleen Freeman, *Ancilla to the Pre-Socratic Philosophers* (Cambridge, MA: Harvard University Press, 1948).

More recent collections of texts are S. Luria, *Democritea* (Leningrad, 1970; original texts of fragments and testimonia with Russian translation and commentary) and C. C. W. Taylor, *The Atomists: Leucippus and Democritus. Fragments: A Text and Translation with a Commentary* (Toronto: University of Toronto Press, 1999; fragments in Greek with facing English translation, testimonia in translation, commentary).

A classic monograph on Leucippus and Democritus is Cyril Bailey, *The Greek Atomists and Epicurus* (Oxford, 1928). Lucid, brief expositions of their thought are found in G. S. Kirk, J. E. Raven and M. Schofield, *The Presocratic Philosophers*, 2nd ed. (Cambridge, U.K., 1983) and in R. D. McKirahan Jr., *Philosophy before Socrates* (Indianapolis and Cambridge, 1994). W. K. C. Guthrie, *A History of Greek Philosophy*, vol. 2 (Cambridge, U.K.: Cambridge University Press, 1965), contains a full discussion and extensive bibliography. Other significant general studies are E. Zeller, *Die Philosophie der Griechen*, 6th ed., revised and enlarged by W. Nestle (Leipzig, 1920), Part I, Sec. 2, pp. 1038–1194; Wilhelm Schmidt in Wilhelm Schmidt and Otto Stählin, eds., *Geschichte der griechischen Literatur* (Munich, 1948), Part I, Sec. 5, pp. 224–349; V. E. Alfieri, *Gli atomisti* (Bari, 1936) and *Atomos Idea*, 2nd ed. (Florence, 1979); J. Barnes, *The Presocratic Philosophers*, 2nd ed. (London and Boston: Routledge and K. Paul, 1982), Chapters 17, 19 (b), 20, 21 (c), 23 (d), 24 (e); P.-M. Morel, *Démocrite et la recherche des causes* (Paris, 1996); and J. Salem, *Démocrite: Grains de poussière dans un rayon de soleil* (Paris: CNRS-Éditions, 1996).

A full discussion of the chronological and biographical data on Democritus is contained in D. O'Brien, "Démocrite d'Abdère" in R. Goulet, ed., *Dictionnaire des Philosophes Antiques*, vol. 2, pp. 649–715 (Paris: CNRS-Éditions, 1994).

LEVINAS, EMMANUEL  
(1906–1995)

Emmanuel Levinas was born in Kaunas, Lithuania, of Jewish parents. His education familiarized him with the Hebrew Bible and the Russian novelists. After having studied at the gymnasiums in Kaunas and Charkow, Ukraine, he traveled to Strasbourg, where he studied philosophy from 1924 to 1929. He spent the academic year of 1928–1929 in Freiburg, where he attended the last seminars given by Edmund Husserl and the lectures and seminars of Martin Heidegger. His dissertation, *La théorie de*

*l'intuition dans la phénoménologie de Husserl*, was published in 1930. In 1930 Levinas settled in Paris, where he worked for the Alliance Israélite Universelle and its schools located throughout the Mediterranean. In 1947 he became the director of the École Normale Israélite Orientale, the training facility for teachers of those schools. In 1961 he was appointed professor of philosophy at the University of Poitiers and in 1967 at the University of Nanterre. In 1973 he moved to the Sorbonne, where he became an honorary professor in 1976. Levinas died on December 25, 1995, a few days before his 90th birthday.

## WORKS

Until World War II most of Levinas's writing focused on introducing the phenomenology of Husserl and Heidegger into France. His early commentaries on their work were collected in *En découvrant l'existence avec Husserl et Heidegger* (1949). His first personal essay was the article "De l'évasion" (1935), whose central question was whether it is possible to evade the totalizing tendency of being. The search for an answer coincided with the beginning of his criticism of Heidegger's ontology. Levinas's first personal book, with the anti-Heideggerian title *De l'existence à l'existant* (*From Existence to Existents* or *From Being to Beings*), was published in 1947. In the same year he gave a lecture series under the title *Le temps et l'autre* (*Time and the Other*), in which some central thoughts of his later work are anticipated. A part of *De l'existence à l'existant* to which Levinas later refers with approval is its phenomenology of *il y a* ("there is"), that is, being in its most general and indeterminate or empty sense, preceding all determination, order, and structure. Levinas describes it as a formless and obscure night and a silent murmur, an anonymous and chaotic atmosphere or field of forces from which no being can escape. It threatens the existing entities by engulfing and suffocating them. As such, being is horrible, not because it would kill—death is not an evasion from it—but because of its depersonalizing character. All beings are caught in the anonymity of this primordial materiality—much different from the giving essence of *es gibt* as described by Heidegger.

The work that made Levinas famous is *Totalité et infini. Essai sur l'extériorité* (1961). As an attack on the entirety of Western philosophy, including Heidegger's ontology, this work tries to show why philosophy has not been faithful to the most important facts of human existence and how its basic perspective should be replaced by another one. The "totality" of the title stands for the absolutization of a panoramic perspective from which reality

is understood as an all-encompassing universe. All kinds of relation, separation, exteriority, and alterity are then reduced to internal moments of one totality. Borrowing from Plato's *Sophist*, Levinas affirms that Western philosophy reduces the other (*to heteron*) to "the Same" (*tauton*). The resulting tautology is an egology because the totalization is operated by the consciousness of an ego that does not recognize any irreducible heteronomy.

The relative truth of the ego's autonomy is shown in a phenomenology of the way in which human beings inhabit the world. Levinas characterizes this "economy" (from *oikos* = house, and *nomos* = law) as vitality and enjoyment of the elements. Implicitly polemicizing against Heidegger's description of *Dasein*'s being-in-the-world, he focuses on the dimension of human eating, drinking, walking, swimming, dwelling, and laboring, a dimension more primordial than the handling of tools and much closer to the natural elements than scientific or technological objectification.

The infinite (*l'infini*), which Levinas contrasts with the totality, is another name for "the Other" insofar as this does not fit into the totality. In order to determine the relation between consciousness, the totality, and the infinite, Levinas refers to René Descartes's *Meditations on the First Philosophy*, in which Descartes insists on the fact that the idea of the infinite is original and cannot be deduced from any other idea. It surpasses the capacity of consciousness, which in it "thinks more than it can think" (see Levinas's *Collected Philosophical Papers*, p. 56). The relation between the ego and the infinite is one of transcendence: The infinite remains exterior to consciousness, although this is essentially related to its "height."

The concrete sense of the formal structure thus indicated is shown through a phenomenology of the human other, whose "epiphany" reveals an absolute command: As soon as I am confronted, I discover myself to be under an absolute obligation. The fact of the other's existence immediately reveals to me the basic ought of all ethics. On this level is and ought are inseparable. Instead of the other (*l'autre* or *autrui*), Levinas often uses the expressions "the face" (*le visage*) or "the speech" (*la parole*, also *le langage*) because the other's looking at me and speaking to me are the two most striking expressions of the other's infinity or "height." As the relation between an economically established ego and the infinite other, the intersubjective relation is asymmetrical: The other appears primarily not as equal to me but rather as "higher" and commanding me. I am responsible for the other's life, a responsibility that puts infinite demands on

me, but I cannot order another to give his or her life for me.

In his second major work, *Autrement qu'être ou au-delà de l'essence* (1974), Levinas continues his analyses of the relationship between the ego and the other but now emphasizes the basic structure of the ego, or rather of the "me" in the accusative, as put into question, accused, and unseated by the other. The relationship is described as nonchosen responsibility, substitution, obsession, being hostage, persecution. Subjectivity (the "me" of *me voici*) is determined as a nonchosen being-for-the-other and, thus, as basically nonidentical with itself, a passivity more or otherwise passive than the passivity that is opposed to activity. Subjectivity is primarily sensibility, being touched and affected by the other, vulnerability.

In the course of his analyses Levinas discovered that the other, me, and the transcendence that relates and separates them do not fit into the framework of phenomenology: Neither the other nor I (me) is phenomenon; transcendence does not have the structure of intentionality. Through phenomenology Levinas thus arrived at another level of thinking. He did not join Heidegger's call for a new ontology, however.

In *Autrement qu'être* Levinas gives a new description of the way being "is": *Esse* is *interesse*; being is an active and transitive "interestingness" (*intéressement*), which permeates all beings and weaves them together in a network of mutual interest. If ontology is the study of (this) being, it is not able to express the other, transcendence, and subjectivity. Transcendence surpasses being. Appealing to Plato, who characterized the good as *epekeina tês ousias*, Levinas points at transcendence, infinity, and otherness as "otherwise" and "beyond" the realm of being (or essence).

The other, subjectivity, and transcendence—but then also morality, affectivity, death, suffering, freedom, love, history, and many other (quasi-)phenomena—resist, not only phenomenology and ontology, but all kinds of objectification and thematization. As soon as they are treated in a reflective discourse, they are converted into a said (*dit*). The saying (*dire*), in which the "otherwise than being" (that which is not a phenomenon, a being, or a theme) addresses itself to an addressee, is lost in the text of the said. However, thematization and objectification are inevitable, especially in philosophy and science, but also in the practical dimensions of law, economy, and politics. The organization of justice cannot do without generalization and grouping of individuals into totalities. The transition from the asymmetrical relation between the other and me to the generalities of justice is founded

in the fact that the other human who, here and now, obligates me infinitely somehow represents all other humans.

How does the intersubjective and asymmetric transcendence differ from the relationship to God? "Otherness," "infinity," and "beyond" do not apply to God in the same way as to the human other. God is neither an object nor a you; no human being can meet with God directly, but God has left a trace. The infinite responsibility of the one for the other refers to an election that precedes freedom. In coming from an immemorial, anachronical "past," responsibility indicates the "preoriginary" "illeity" of God. The *il* or *ille* of "the most high" is sharply distinguished from the chaotic anonymity of *il y a*; the dimensions of economy, morality, and justice separate the indeterminacy of being from the beyond-all-determinacy of God. However, as the practical and theoretical recognition of the relationship between God and humans, religion cannot be separated from ethics: The only way to venerate God is through devotion to human others.

Besides the two books summarized here, Levinas wrote many articles. Most of these were collected in *Humanisme de l'autre homme* (1972), *De Dieu qui vient à l'idée* (1982), *Hors sujet* (1987), and *Entre nous* (1991).

Like all other philosophers, Levinas has convictions that cannot be reduced to universally shared experiences, common sense, or purely rational principles. In addition to his philosophical work he wrote extensively on Jewish questions from an orthodox Jewish, and especially Talmudic, point of view. In his philosophical writings he quotes the Bible perhaps as often as William Shakespeare or Fëdor Dostoevsky, but these quotations are not meant to replace philosophical justification of his assertions. Phenomenological rigor and emphasis are typical of his method, even where he points beyond the dimensions of phenomena and conceptuality.

### Bibliography

A complete bibliography of primary and secondary texts published between 1929 and 1989 is given in Roger Burggraeve, *Emmanuel Levinas; une bibliographie primaire et secondaire (1929–1985) avec complément 1985–1989*. Leuven: Peeters, 1990.

The most important philosophical books of Levinas are: *La théorie de l'intuition dans la phénoménologie de Husserl*. Paris: Alcan, 1930; 2nd ed., 1963. Translated by A. Orianne

- as *The Theory of Intuition in Husserl's Phenomenology*. Evanston, IL: Northwestern University Press, 1973.
- De l'existence à l'existant*. Paris, 1947; 2nd ed., 1978. Translated by A. Lingis as *Existence and Existents*. The Hague: Nijhoff, 1978.
- Le temps et l'autre*. Montpellier, 1979 (2nd ed. of Levinas's contribution to *Le choix, le monde, l'existence* [Paris, 1948]). Translated by R. Cohen as *Time and the Other*. Pittsburgh: Duquesne University Press, 1987.
- En découvrant l'existence avec Husserl et Heidegger*. Paris, 1949; 2nd ed., Paris: Vrin, 1967. Partially translated by A. Lingis in *Collected Philosophical Papers (v. infra)*.
- Totalité et Infini. Essai sur l'extériorité*. The Hague: Nijhoff, 1961. Translated by A. Lingis as *Totality and Infinity: An Essay on Exteriority*. Pittsburgh: Duquesne University Press, 1969.
- Humanisme de l'autre homme*. Montpellier: Fata Morgana, 1972.
- Autrement qu'être ou au-delà de l'essence*. The Hague: Nijhoff, 1974. Translated by A. Lingis as *Otherwise than Being or Beyond Essence*. The Hague: Nijhoff, 1981.
- De Dieu qui vient à l'idée*. Paris: Vrin, 1982.
- Collected Philosophical Papers*. Translated by A. Lingis. Boston: Nijhoff, 1987. Contains the English translation of twelve thematic essays from several volumes and journals.
- Hors sujet*. Montpellier, 1987.
- Entre nous: Essais sur le penser-à-l'autre*. Paris: Bernard Grasset, 1991.

## LÉVY-BRUHL, LUCIEN (1857–1939)

Lucien Lévy-Bruhl, the French philosopher and social anthropologist, was educated at the University of Paris and the École Normale Supérieure. He occupied the chair of philosophy at the Lycée Louis-le-Grand from 1885 to

1895, when he became *maître de conférences* at the Sorbonne; in 1908 he was appointed titular professor. In 1916 he became editor of the *Revue philosophique*.

Lévy-Bruhl's early work was devoted to the history of philosophy, particularly that of Auguste Comte. While still under the influence of Comte and also of Émile Durkheim, he published *La morale et la science des moeurs* (Paris, 1903; translated by E. Lee as *Ethics and Moral Science*, London, 1905). It stressed the need for detailed empirical studies of the diverse moral attitudes and ideas of different societies as well as the adaptation of these ideas to the social structure of the group. He considered such a description and explanation as a preliminary to a possible applied science of morals, which would give men the same power to modify social life as physical technology gives them over natural phenomena.

Lévy-Bruhl did not develop this idea of a moral technology but devoted most of his life to investigating an extremely wide range of anthropological data derived from the reports of other observers. The interest of his work lies in the theoretical ideas that he applied to this material.

Lévy-Bruhl argued that the behavior of men in primitive societies must be understood in terms of Durkheim's concept of "collective representations," which are emotional and mystical rather than intellectual. The primitive man's world is dominated by occult powers, and his thought is "prelogical," following a law of participation and quite indifferent to what civilized man would regard as self-contradictions. For example, the members of a totemic group may regard themselves as actually identical with their totem, as belonging to a continuum of spiritual powers, rather than as existing as distinct individuals. Prelogical concepts imply no systematic unity but "welter, as it were, in an atmosphere of mystical possibilities" (*How Natives Think*, Ch. 3). Space, for instance, is conceived, not as a homogeneous whole, but in terms of the mystical ties binding each tribe to a particular region, the structure of the ties being understood in terms of the various occult forces to which the life of the tribe is subject.

Primitive man is similarly indifferent to conceptions of causality as understood in civilized cultures. For him there is no natural order within which perceptible phenomena are causally interconnected, but, equally, nothing happens by chance. Events are brought about directly, not through any mechanism of secondary causes; they are effected by the imperceptible denizens of an occult realm who have no definite spatiotemporal location and who may be felt as present in several places simultaneously.

Durkheim's followers have criticized Lévy-Bruhl for failing to bring out the connections between primitive collective representations and social structure. He has also been accused of overstressing the extent of prelogical elements in primitive thought. In attempting to reconcile the existence of fairly highly developed arts and crafts in primitive tribes with his denial that such tribes thought at all in terms of logical and causal connections, he held that such manual skills are not based on reasoning but "are guided by a kind of special sense or tact," refined by experience without benefit of reflection. Lévy-Bruhl's most serious philosophical shortcoming, perhaps, is his failure to see anything problematic about the nature of logic itself and the role it plays in civilized life. His identification of logical thought with the thought of Western civilization prevented him from perceiving many important continuities and analogies between primitive and civilized attitudes and practices.

## LEWIS, CLARENCE IRVING (1883–1964)

Clarence Irving Lewis, the American epistemologist, logician, and moral philosopher, was born in Stoneham, Massachusetts, and educated at Harvard University (AB, 1906; PhD, 1910). He taught at the University of California from 1911 to 1920 and at Harvard from 1920 until his retirement in 1953; after 1930 he was the Edward Pierce professor of philosophy. He delivered the Carus Lectures in 1945 and the Woodbridge Lectures in 1954.

Lewis was a student and critic of modern extensional systems of logic and developed a modal logic based on the notion of strict implication. In epistemology and ethics, he was a pragmatic Kantian.

Lewis internalized within himself the great dialogue on knowledge and reality which began with René Descartes and continued with the British empiricists, Immanuel Kant and the German idealists, and the American pragmatists. It may be said that this tortuous development, both in its long history and in the intellectual life of Lewis, is the attempt of the modern mind to achieve consistency and adequacy in its conceptual foundations.

The basic commitments of any philosopher, whether formulated or not, concern the nature and modes of knowledge; they not only determine what is philosophically problematic for him but also determine how intelligibility can be achieved. Lewis modifies the classical certainty theory of knowledge, which maintains that knowing is an infallible state of mind. He contends that it does not make sense to talk about knowledge where there is no possibility of error. Knowing, according to him, is an assertive state of mind that is subject to appraisal as correct or incorrect by virtue of its relationship to what it is about, and also subject to appraisal as justified or unjustified in terms of its grounds or reasons. Thus the apprehension of a sensory given, or, in other words, the occurrence of an appearance, the classical paradigm of empirical knowledge, is not regarded by Lewis as knowledge, for there is no possibility of error. The apprehension of the appearance and its existence are indistinguishable.

Yet Lewis's departure from the tradition is not great. He, too, insists that at the foundation of our knowledge structure there must be certainty and that this is found in knowledge of sensory appearances. This certainty, however, does not reside in the apprehension of the given. Sensory appearances may be linguistically reported in "expressive" language, which denotes and signifies only appearances. Although there can be no error in the apprehension of a given appearance, it is possible to tell lies

about it. Therefore, such reports are statements with truth-values. But still there is no knowledge, for no judgment is made in which the person could be in error. Knowledge is born at the level of what Lewis calls “terminating judgments,” which are of the form “‘S being given, if A then E,’ where [in expressive language] ‘A’ represents some mode of action taken to be possible, ‘E’ some expected consequence in experience, and ‘S’ the sensory cue.” For example, there being a red patch in my visual field, if I seem to turn my head to the left, the red patch moves to the right. Such a judgment is not merely the apprehension of a given, or the linguistic expression of such. It embodies a prediction that the red patch will be displaced to the right if the specified condition is fulfilled, which Lewis contends is conclusively verified by the occurrence of the mentioned appearances.

Thus Lewis locates certainty in verified terminating judgments, which are about sensory appearances. Furthermore, he claims that all knowledge about the world is grounded in and derived from such certainties. Although this is more sophisticated than the traditional empiricist’s account, it comes to much the same subjectivistic conclusion, namely, that the direct objects of knowledge are subjective and private, and therefore falls heir to all the problems of modern subjectivism. Lewis’s major works are devoted to the central and toughest of these problems: how to make intelligible, from within these epistemological commitments, empirical knowledge of the objective world; a priori knowledge, including mathematics, logic, and philosophy itself; and value claims and normative judgments.

### EMPIRICAL KNOWLEDGE OF THE OBJECTIVE WORLD

The paradigm of empirical knowledge for Lewis is the verified terminating judgment. It alone can be conclusively verified. All other empirical judgments are nonterminating. They may be shown to be probable but cannot be established with certainty. The probability value they have is conferred upon them by the verification of terminating judgments that they entail. Therefore, a necessary condition for a nonterminating judgment to be confirmable in any degree, and thus meaningful, is for it to entail terminating judgments.

Any statement that purports to be about objects other than appearances, such as physical objects, is nonterminating, and insofar as it is confirmable and therefore meaningful, it entails terminating judgments, which are about appearances only. It would seem that the full meaning of such a statement would be expressible in the

terminating statements entailed by it and that, since these statements are about appearances only, the physical-object statement itself would really refer only to appearances. This would be phenomenalism.

Lewis resists this conclusion. He gives two arguments for realism. The first is that although a physical-object statement is intensionally equivalent to an inexhaustible set of terminating statements and the terms in the latter refer only to appearances, the terms in the physical-object statement genuinely denote physical objects. Thus we have two sets of statements, phenomenalistic and physical-object statements. For each physical-object statement there is a set (although inexhaustible) of phenomenalistic statements intensionally equivalent to it. By confirming the phenomenalistic set we confirm its equivalent physical-object statement with the same degree of probability. Yet the two are about radically different kinds of objects, and from knowledge of appearances we derive knowledge of physical objects.

This argument turns upon his theory of meaning. Lewis distinguishes four modes of the meaning of terms: (1) *denotation*, “the class of all actual things to which the term applies” (for example, the denotation of “man” is the class of all actual men, past, present, and future); (2) *comprehension*, “the classification of all possible or consistently thinkable things to which the term would be correctly applicable” (for example, the comprehension of “man” includes not only actual men but those who might have been but were not, like the present writer’s sisters, since he has none); (3) *signification*, “that property in things the presence of which indicates that the term correctly applies, and the absence of which indicates that it does not apply” (for example, the property “rationality” is often regarded as included in the signification of “man”), and (4) *intension*, which consists of (a) linguistic intension or connotation, all other terms which must be applicable to anything to which the given term is applicable (for example, “animal” must be applicable to anything to which “man” is applicable); and (b) sense meaning, the criterion in mind, an imagined operation “by reference to which one is able to apply or refuse to apply the expression in question in the case of the presented, or imagined, things or situations” (for example, the sense meaning of “kilogon” is the imagined operation of counting the sides of a plane figure and the completion of the operation with the count of 1,000). Since he regards “propositions,” statements with the assertive factor extracted (for example, “Mary’s baking pies”), as terms, these modes of meaning apply to them as well. He further distinguishes between the “holophrastic” meaning of a statement, its

meaning as a whole, and its “analytic” meaning, the meaning of its terms.

His argument is that although the holophrastic intensional meaning of a physical-object statement is the same as that of a set of phenomenalistic statements, the physical-object statement and its corresponding set of phenomenalistic statements are different in their analytic denotive meaning, the former denoting physical objects and the latter appearances.

Lewis rightly maintains that any two expressions that have the same intension have the same signification. Yet if a term denotes a physical object, it must signify a physical-object property. Therefore such a term could not have the same signification as a phenomenalistic term. Hence it seems that a physical-object statement could not have the same intension as a set of phenomenalistic statements.

Lewis senses this difficulty and seeks to avoid it by speaking of intension, in the form of sense meaning, as “that in mind which refers to signification.” Appearances are said to signalize objective properties or states of affairs. Yet he gives no account of how this is possible for beings who can apprehend only appearances. How can appearances, as simple occurrences, be signs of anything other than other appearances? It would seem that the only way out of this subjectivistic trap is to regard appearances not as simple occurrences or objects of apprehension but as intentional in nature, as experiences of physical objects that embody truth claims about them which can be assessed as true or false on the basis of their consistency or lack of it with the claims of other experiences.

Lewis’s second argument for realism turns upon the interpretation of “if ... then ...” in terminating judgments. He regards it as a contrary-to-fact conditional, that is, he claims that the truth of the conditional as a whole is independent of the truth-value of the antecedent and therefore may be significantly asserted when the antecedent is known to be false. Therefore, since it does not express a logical relation of entailment or a truth-functional relationship, it must express a real connection, perhaps causality, that holds between the facts or states of affairs located or referred to by the antecedent and the consequent of the conditional sentence. Belief in a real world, he maintains, is belief in such contrary-to-fact conditionals.

It is not clear how this is an argument for realism. Why must independent physical objects be assumed to account for the contrary-to-fact character of terminating

judgments? Why couldn’t the “real” connection hold between kinds of appearances?

Furthermore, if terminating judgments are to be interpreted in the manner of the contrary-to-fact conditional, does this not compromise their conclusive verifiability? It would seem to introduce an element of generality that would transcend any specific sequence of subjective experiences. In fact, Lewis himself, for other reasons, held that no terminating judgment of the form “*S* being given, if *A* then *E*” is strictly entailed by a physical-object statement. The most we can say, he concluded, is “If *P* [physical-object statement], then when presentation *S* is given and act *A* is performed, it is more or less highly probable that *E* will be observed to follow.” Since the statement is inconclusive, it seems that he has given up the terminating character of “terminating” judgments.

Lewis has not, it seems, made a convincing case for realism from within his phenomenalistic foundations. Some have concluded that it is impossible to do so and that the only way out of phenomenalism is to abandon the subjectivistic starting point itself.

## A PRIORI KNOWLEDGE

The a priori disciplines, namely, mathematics, logic, and philosophy, were the stronghold of classical rationalism. They were regarded as yielding knowledge, grounded in rational intuition, about the essential and necessary structure of the world. Empiricists, for the most part, claim that such knowledge is only intralinguistic, that it consists of analytic truths, which are said to be uninformative about the world.

Lewis subscribes to the view that all “a priori truth is definitive in nature and rises exclusively from the analysis of concepts.” Unlike many empiricists, however, he is not content with merely characterizing a priori knowledge as analytic. For him, concepts, their logical relations, and their relation to the data of sense and the structure of the world are highly problematic. He regards concepts, logical relations, and a priori truths arising from them as the peculiar characteristics of mind. He sets them in contrast with the given data of sense experience, which he regards as brute fact, unlimited and unaffected by the conceptual structure. But these givens would be unintelligible without the a priori criteria of classification provided by mind, criteria which are involved not only in talk about things but even in the experience of objects. Thus, the necessary connections of concepts are embedded in perception, and analytic truths, far from being trivial and only intralinguistic, formulate the a priori structure of the world as experienced and known.

Our basic conceptual structure, and thus our a priori truths, are not fixed and eternal. They consist of deep-seated attitudes grounded in decisions that are somewhat like fiats in certain respects and like deliberate choice in others. There is nothing in our conceptual structure that is not subject to change in the face of continuing experience. This includes such basic decisions as the decision that whatever is to count as real, in contrast with the hallucinatory, must stand in causal relations with other real things. Even the laws of logic, “the parliamentary rules of intelligent thought and action,” are subject to change. The only test applicable is pragmatic, the achievement of intelligible order with simplicity, economy, and comprehensiveness in a way that will be conducive to the long-run satisfaction of human needs. Thus, Lewis holds to a pragmatic theory of a priori truth but not of empirical truth.

Philosophy, according to Lewis, is a reflective, critical study of mind and its a priori principles as found in “the thick experience of everyday life,” and thus in “the structure of the real world which we know.” Although it studies what is implicit in experience, it is analytic and critical in method rather than descriptive. Its function is not only to formulate the conceptual structure built into experience and thought but to sharpen and to correct it. Thus philosophical claims may be analytic in character, like “There is an intelligible order in the objective world.” Lewis takes this statement to be analytic on the ground that an intelligible order is an essential mark of the objective world. Whatever lacks a certain minimum order is only subjective, private experience, like dreams and hallucinations. Philosophical claims also may be critical and revisionary, recommending some change in our categorical attitudes, such as “Only the physical is real.”

Lewis’s theory of the a priori places the conceptual framework between two sets of givens, the presentations of sense, to which concepts apply to yield empirical knowledge, and the values in terms of which the a priori structure is pragmatically tested. It seems that both sensory experiences and values would have to be free of a priori assumptions in order to serve the function ascribed to them. This is a difficult doctrine to maintain.

#### VALUE CLAIMS AND NORMATIVE JUDGMENTS

The ultimate test of the a priori conceptual framework, according to Lewis, is “the long-run satisfaction of our needs in general.” It would seem that value judgments would have to be independent of the conceptual framework that is being pragmatically tested if the test is to be

clear-cut and not beg the question. But obviously this would be impossible in the case of basic issues. Although Lewis does not face the problem in these terms, he may be said to blunt the criticism by locating values among sense presentations and by invoking unavoidable imperatives that would be operative in any conceptual framework.

Value, in its most primitive sense, has to do with sense presentations. It is not so much a specific phenomenal quality as a mode or aspect of the given, namely, the given as gratifying or grievous. The only thing that is intrinsically good is liked or wanted subjective experience. In addition to the immediately found intrinsic value of an experience, it may be said to have contributory value by virtue of the contribution it makes to the total value quality of the conscious life of which it is a part. Such a life, he contends, is not simply a sum of its parts. So the contributory value of an experience is quite different from its intrinsic value. Objects of experience are said to be extrinsically good or bad according to their capacity to produce experiences which are satisfying or unpleasant.

Thus, for Lewis, value knowledge is a form of empirical knowledge. There are both terminating and nonterminating value judgments. The former are subjective statements of intrinsic and contributory value; the latter are objective statements about extrinsic values. Judgments of right and wrong, however, are not empirical in character. They are determinable only by reference to rules or principles that refer to values in their prescriptions. He regards the basic rational imperative to be so to think and so to act that later you will not be sorry. The only way this can be achieved is for decisions to be guided by objective knowledge rather than merely by the affective quality of immediate experience. In the area of morals, this requires that we respect others as the realities we know them to be, “as creatures whose gratifications and griefs have the same poignant factuality as our own; and as creatures who, like ourselves, find it imperative to govern themselves in light of the cognitive apprehensions vouchsafed to them by decisions which they themselves reach, and by reference to values discoverable to them.”

Any attempt to prove the validity of such principles can only appeal to an antecedent recognition of them. They must be recognized by all who make decisions, all who think and act. Genuine skepticism with regard to judgments of right and wrong, good and bad, would be impossible, for on such a basis even doubt itself would be meaningless.

The question remains: Is the conceptual framework in which normative and value knowledge is formulated pragmatically testable, and, if so, just what could such a pragmatic test amount to? If it is not so testable, then it would seem that in the end Lewis is not a pragmatist after all.

## LEWIS, C. S. (CLIVE STAPLES) (1898–1963)

C. S. Lewis was a British teacher, writer, and critic. He was born and raised in Belfast but spent most of his academic career at Oxford. After having volunteered for the army and subsequently getting wounded, in 1917, he returned to Oxford and took first class honors in "Greats" (philosophy and classics). Shortly thereafter he taught philosophy at Oxford as a substitute for Edgar Carrit, his former tutor in philosophy while Carrit was on leave as a visiting professor at the University of Michigan. Finding no opportunity for teaching in classics or philosophy, and having also gotten first class honors in English, Lewis was elected to a fellowship in English at Magdalene College, where he taught for thirty years. Toward the end of his academic career he was appointed to a newly created Chair of Medieval and Renaissance English at Cambridge. His strictly academic work was concentrated on the ideas rather than the literary forms of medieval and renaissance English writers.

Early in his career at Oxford Lewis became a convert, first to theism and then to Christianity. During World War II he was asked to give lectures about Christianity on the BBC: Printed in book form, these were the basis of his most famous popular work, *Mere Christianity* (2001 [1942]). Other popular works were *The Problem of Pain* (2001 [1940]), *Miracles* (2001 [1947]), and *The Screwtape Letters* (2001 [1942]). In 1945, Lewis argued with G. E. N. Anscombe about a claim in Chapter 5 of *Miracles* that naturalism is self-refuting, for it says that all our thoughts are ultimately traceable to the blind working of chance and that no thought is valid if it can be fully explained as the result of irrational causes. Anscombe distinguished between "irrational" causes and "nonrational" causes and argued that being the result of "nonrational" causes does not make our reasoning invalid. Lewis, in reply, says the "valid" in the logician's sense is not the correct word for what he meant and distinguished between "reasons" and "causes" (Hooper 1979). Some have thought that he lost that argument. He revised the chapter of *Miracles* which Anscombe had criticized, and Anscombe, at least, felt that the revision answered much of her original objections (Purtill 2004). Late in his life (in 1957), Lewis married Helen Joy Davidman, who was dying of cancer. She surprisingly (and perhaps miraculously) recovered and they spent three happy years together.

After her death, Lewis wrote (anonymously) *A Grief Observed* (2001 [1961]), which some scholars have held

demonstrates that he had lost his faith, or at least his belief in the rational justification of Christianity. However, a more careful reading shows that his own description of Christianity to a friend is true: “It ends in faith, but begins with the blackest of doubts en route” (unpublished letter quoted in Purtil 2004, p. 25). It is useful to compare this book with two of his later works: *Till We Have Faces*, a fictional account of a woman who began writing a book as a complaint against the gods (the account is set in classical times) and “ends in faith”; and *Letters to Malcolm* (2002 [1964]), which touches on some of the same themes.

Lewis was, in this author’s judgment as well as the judgment of other critics, a great master of English prose and a powerful writer of fiction with underlying religious themes: the seven books of the *Chronicles of Narnia*, the “space” trilogy, and *Till We Have Faces*.

Philosophically speaking, Lewis’s work, both nonfiction and fiction, has a number of characteristics:

(1) He argues for his points on the basis of reason and experience. As he says in an essay, “There is, of course, no question ... of belief without evidence ... or in the teeth of evidence ... if anyone expects that, I certainly do not” (Lewis 2001 [1955], p. 17);

(2) He thinks of faith as a rational acceptance and of “temptations against faith” as emotional reactions when we find it would be much more convenient *not* to believe;

(3) He accepts miracles and uses them as evidence for Christianity, first refuting the arguments of Hume and others against the *possibility* of miracles or the possibility of knowing them, and then arguing historically that miracles have occurred;

(4) Miracles, as Lewis defines them, depend on the existence of God. Lewis argues for God’s existence using variations of the moral argument and the argument from design, especially a version of what Victor Reppert has called “the argument from reason” which argues that to really trust our reason we need the existence of God. For the moral argument, Lewis agrees with other philosophers that “if God does not exist anything is permitted” and by contraposition that “if not everything is permitted [as he argues from our moral experience] then God must exist.”

(5) Lewis contrasts Christianity with other forms of belief—such as naturalism, Hinduism, and so on—

and argues that Christianity explains the facts of experience better than other forms of belief.

(6) Lewis grants that the problems of moral and natural evil are the most powerful against a belief in a loving, omnipotent God, and addresses both in *The Problem of Pain* and elsewhere.

Professional philosophers may find many of Lewis’s arguments oversimplifications; Lewis would probably grant this for his more popular works, which were intended for intelligent nonprofessionals. However, this leads to a situation where philosophical argument can begin. What are the alleged oversimplifications and how can they be repaired? Lewis’s experience with Anscombe showed he was capable of doing this, as does his work in less popular works addressed to academic or clerical audiences.

The talent that made him a good writer of fiction carries over to his nonfictional works; he is a poet, as well as a logician, and employs a gift for metaphor and analogy in his statements of arguments. Lewis has been called “perhaps the twentieth century’s most popular proponent of Faith based on reason” (Nicholi 2002, p. 3). Many opponents of Christianity have taken Lewis’s arguments seriously, especially those scholars who, such as Antony Flew, wish to be fair to Christianity and try to refute its best arguments. Many supporters of Christianity, both nonprofessional and academic alike, would give Lewis major credit for beginning the process that led them to Christianity.

## LEWIS, DAVID

(1941–2001)

David Lewis was born in Oberlin, Ohio. He studied as an undergraduate at Swarthmore College before gaining a PhD in philosophy from Harvard University in 1967 where he studied with Willard van Orman Quine. His first job was at the University of California at Los Angeles, where he worked from 1966–1970, before moving to Princeton University where he worked for the rest of his career. Lewis published four monographs and more than one hundred papers, most of which have been gathered into five volumes of his collected papers. Lewis made contributions to virtually every area of contemporary Anglo-American philosophy but is probably best known for his contributions to metaphysics, in particular, his work on modality (necessity and possibility) and possible worlds and also his theories of laws of nature, causation, and chance. His work in the philosophy of mind has also been influential, as has his work on conventions and language.

## MODALITY

Some of Lewis's best known work is in the metaphysics of modality: that is, his account of the nature of necessity and possibility. Lewis thought it was important to make sense of what we are doing when we talk about different possibilities that seem open, or when we say that certain facts (such that  $2+2=4$ ) are necessary, or that it is impossible for them to be otherwise. Lewis held, along with others whose claims about possibility and necessity were

to be understood as implicitly generalizing over possible worlds, complete ways things could be: To say something was possible was to say that it occurred in at least one possible world, and for something to be necessary was for it to obtain in all possible worlds. Where Lewis was nearly unique was his account of what these other possible worlds were.

According to Lewis, possible worlds were large spatiotemporal regions filled with objects and events of the same kind as those in our world, except, of course, that every possible sort of thing is found in one world or other. So Lewis's worlds contain people and trees and galaxies and tables; but also dragons, extra-spatiotemporal dimensions, ghosts, and so on. This construal of possible worlds became known as *modal realism*. Despite the counterintuitive nature of this theory, Lewis showed that it brought with it many advantages, and he argued that attempts to construe possibilities as some sort of abstract object (*ersatzism* about possible worlds, in Lewis's vocabulary), failed to provide an analysis of modality, and many varieties suffered crippling internal problems.

Lewis also suggested a novel way of dealing with *de re* necessities and possibilities (possibilities or necessities for an object rather than as concerning the status of a proposition). Lewis argued that these were best analyzed using counterpart theory: where what is possible for me is what happens for one of my counterparts in another world. Since Lewis held that, strictly speaking, each possible individual was part of only one possible world, he could avoid some of the puzzles about trans-world criteria for identity. In addition, counterpart theory allowed more flexibility than literal identity would. Lewis argued, for instance, that the counterpart relation need not be transitive (so something that could happen to one of my counterparts need not be something that is possible for me) though a failure of transitivity is harder to understand if it is literal identity across possible worlds that is required for *de re* possibility (i.e., if something has to be literally happening to me in some other possible world in order for it to be possible for me). Lewis also allowed that there were multiple counterpart relations, which might give rise to multiple kinds of *de re* possibility for an object. So, for example, what the counterparts of an object are when that object is considered as a statue might be different from what the counterparts of that object are when the object is considered to be a lump of bronze. Lewis could thus allow that what we appropriately say is possible for the statue is different from what we appropriately say is possible for the piece of bronze even though the two objects might nevertheless be identical.

## COUNTERFACTUALS, LAWS, CAUSATION, AND CHANCE

Issues about contrary-to-fact-conditionals, laws of nature, causation, and chance are often thought to be connected, and Lewis's contributions to these topics formed a unified neo-Humean system. Lewis's book *Counterfactuals* (1973a) offered an analysis of conditionals of the form *if p, it would have been the case that q* in terms of possible worlds: a conditional such as *if dolphins had had legs, they would have walked on land* is true if and only if the *nearest* possible world where dolphins have legs is one where dolphins walk on land. *Nearness*, in turn, is analyzed as overall similarity in salient respects: it is thus context-dependent, and Lewis had more to say about what sort of similarity is significant for particular sorts of these so-called counterfactual conditionals, for example the ones employed in causal reasoning.

This analysis of counterfactual claims has several advantages. It is formally tractable, yielding a logic of counterfactual judgments with some initially surprising features that do seem to correspond to features of our ordinary counterfactual judgments. For example, Lewis's system delivers the result that *strengthening the antecedent* is invalid: that is, the inference (if *p* then *q*), therefore (if *p* and *r* then *q*) is invalid. But consider this argument: If I leave now, I will catch the train; therefore, if I leave now and am assassinated on the way I will catch the train. The premise might well be true and the conclusion false if I run no real risk of being assassinated.

In addition, since the analysis of these conditionals does not itself appeal to, for example, dispositions or causation, it leaves the way free for counterfactual analyses of other puzzling parts of metaphysics. And, indeed, Lewis championed a counterfactual analysis of causation: At a first pass, an event *C* causes an event *E* if and only if both *C* and *E* occur and had *C* not occurred, *E* would not have occurred either. A lot more than this first pass is required for an adequate counterfactual account of causation: Sometimes *E* would have happened in any case, even without *C*, for example, if *E* is overdetermined. Lewis experimented with a number of counterfactual theories of causation: Their development can be seen in Lewis 1973b (and see especially the postscripts in Lewis 1986b), Lewis 1979a, and most recently Lewis 2000 and Lewis 2004.

The connection between counterfactuals and causation, on the one hand, and laws of nature, on the other hand, is slightly circuitous in Lewis, but it is another key connection in his overall system. Lewis defended a regularity theory of laws of nature: Following Ramsey, Lewis

held that the laws of nature were given by the set of generalizations that provided the best tradeoff of simplicity and strength in capturing the goings-on of the world. Since the laws supervene on the patterns of particular matters of fact, at this point, at least, Lewis's metaphysical posits are minimal.

Even though the laws are only descriptions of certain privileged regularities, they make a difference to which counterfactuals are true, in Lewis's system, because similarity with respect to whether our laws hold is one of the most important components in the kind of similarity relevant for the nearness relation between possible worlds central to Lewis's analysis of counterfactuals. So when some event *A* would follow as a matter of law from another event *B*, the nearest world where *A* occurs will be one where *B* also does. Thus mere patterns of particular occurrences give rise to laws of nature, counterfactual dependencies, and so to causation—at least, if Lewis is right. Lewis extended his regularity framework to handle objective chances as well: Another member of the *nomic family* was explained, ultimately, in terms of regularities in particular events.

## MIND

Lewis made contributions to several areas of the philosophy of mind. First in importance is his defense of an identity theory of the mind. Lewis characterized mental states according to the role attributed to them in our ordinary *folk* understanding of the mind: A belief, for example, is a state that tends to go together with desires with certain contents to produce certain sorts of actions. Folk psychology, when articulated, describes causal *roles* for each different sort of mental state (beliefs, desires, pains, emotions), and these roles are interdefined so that the typical causal profile of a belief is specified partly in terms of other beliefs it tends to cause, partly in terms of perceptions that tend to cause it, how it interacts with desires, and so on.

Armed with this role statement of the typical causes and effects of mental states, Lewis then argued that mental states are identical to those physical states in us that play these causal roles: So Tom's belief that it is raining is identical to the brain state of his that is typically caused by the sight and sound of rain, and typically goes together with other brain states to yield umbrella-grabbing behavior, and so on. This may well mean that which type of physical state is identical to which type of mental state may vary from subject to subject: Lewis says that which physical state is identical to a given mental state depends on what causal roles that state typically plays in the kind

of thing that has it. So in humans pain will be a certain sort of brain state while in advanced robots it may be some electronic state, and in extraterrestrials it might be a matter of how gases are distributed within internal bladders.

This typical-for-the-species criterion allows both for *multiple realizability*: pain-in-aliens or pain-in-invertebrates may not be the same physical state as pain-in-humans; and we loosen the behaviorist insistence that pain must be the state, whatever it is, that produces pain behavior since, for example, an atypical human may have the state that typically causes pain reactions but makes no outward show of it, or even engages in some nonstandard behavior (imagine a *madman* who whistles, but shows no discomfort, whenever he is in the state that produces pain behavior in normal humans). The view is still a type–type identity theory, according to Lewis, because, for example, the type pain-in-humans can be identified with a particular physical property (e.g. C-fiber-firing-in-humans) even though there is no unified physical type corresponding to *pain* or *belief* simpliciter.

## LANGUAGE AND CONVENTION

In Lewis's first book, *Convention* (1969), he developed a theory of conventions as patterns of mutual expectation and conditional intentions. Roughly, according to Lewis, there is a convention in a population to act in a certain way in certain circumstances if everyone does tend to behave in that way, everyone has the conditional intention to continue behaving that way, conditional on everyone else so acting, and this is common knowledge. Finally, there must also be some other alternative action that people are deciding against: We all breathe oxygen, intend to continue and know that we intend to continue, but this does not make our practice of oxygen-breathing conventional since we all have no choice. He claimed these patterns could arise fairly spontaneously (certainly without the existence of an explicit agreement) and that they tended to arise to solve coordination problems: common cases of collective action where everyone does better by coordinating their activities than if everyone does their own thing. (A decision about which side of the road to drive on is an example: The most important thing is not whether people drive on the left or right hand side but, rather, that either everyone does the one or everyone does the other.)

Lewis argued that we could understand what it was for a population to use a language as a matter of convention, in his sense. In "Language and Languages" (1975), Lewis explained how we could integrate the formal,

abstract theories of languages as functions from expressions to truth-conditions, on the one hand, with theories of language that concentrate on practices of language usage. Lewis also made significant contributions to the formal theory of language and philosophical semantics—his "General Semantics" (1970) is a prime example. Lewis was also responsible for a lot of work exploring the role of context in language: His "Scorekeeping in a Language Game" (1979b) is a classic in this area.

## LI AO

(774?–836)

Li Ao is perhaps the thinker in Tang China (618–907) who contributed most to a new version of Confucian philosophy that addressed issues of human nature and spiritual cultivation. By Li's time, questions in this area had been left to Buddhism and Daoism for centuries, whereas the intellectual elite in general considered Confucianism solely the authority in family and political lives. Li's importance as a thinker comes entirely from a single treatise: the *Fuxing shu* (Writings on returning to one's true nature). It is arguably the first post-Han (206 BCE–220 CE) text that gave an original treatment on the topics of human nature and spirituality from a Confucian stance.

The theme of the *Fuxing shu* is how to become a sage, the Confucian ideal of personality. Li holds that a sage is a person who has realized his "nature" (*xing*), the character of which can be described as "sincerity" (*cheng*). The nature of human beings is bestowed on them by heaven, and all people share the same nature. The reason why hardly anyone becomes a sage is that people's "emotions" (*qing*) obscure their true nature.

As to the method of becoming a sage, Li contends that if one quiets down and thus clarifies one's emotions, one's nature will be revealed and will direct one's life. One can then naturally act in a proper manner—that is, in accord with Confucian behavioral norms. The central point here is that the true nature of humans only exists in the state of tranquility. Yet tranquility of one's nature is not equivalent to suspension of emotions, because the latter will inevitably shift to a state of movement. People should learn to respond to the world directly with their true nature. The nature that is at the same time tranquil and able to have a full control of one's life exists beyond the level of emotions.

At least two issues regarding the *Fuxing shu* deserve attention here. The first is the subject of this treatise. The search for sagehood through self-cultivation was a significant notion in classical Confucianism, but went almost absent after the Han. It was owing to the Buddhist concern with Buddhahood that the perfection of human existence through spiritual cultivation became a major issue in medieval Chinese thought. Li's revival of a dormant Confucian subject is in itself an indication that the *Fuxing shu* represents a Confucian response to the centuries-old dominance of Buddhism and Daoism in the realm of metaphysical and spiritual philosophy. Li's project anticipates the endeavor of neo-Confucianism in Song times (960–1279).

Then there is the much studied and debated issue: the sources of the originality of the *Fuxing shu*. It is clear that medieval Buddhism and Daoism not only gave birth to the theme of Li's treatise, but also affected its ideas in a substantial way. The sharp contrast between "nature" and "emotions" is a case in point. This distinction is not a salient feature of classical and Han Confucianism. Even for those Confucian thinkers believing that moral values were rooted in the essence of human beings, goodness did not just exist in one's nature. It was more important to realize people's moral potential in their actual lives filled with all kinds of emotions. Simply put, in early Confucianism there was no such notion that a return to one's nature, defined as the original state of human existence, represented the perfection of human life. This idea, which is at the core of Li's theory, owed its origins principally to classical and religious Daoism. The most crucial formative force behind this idea seems to be the fundamental Daoist belief that the ideal state of life lies in its reunion with its roots—indeed with the "primordial breath" (*yuanqi*) of the universe.

Although Li borrows heavily from religious ideas current in his time, it is unmistakable that his aim is providing a theoretical framework for a Confucian way of self-cultivation. Li emphasizes that once revealed, one's nature will lead to correct knowledge and actions, that is, those in line with Confucian values. One may say that Li uses a great deal of Buddhist and Daoist material to build a Confucian house. He was one of the rare individuals in the history of ideas to really make a breakthrough.

### LIAR PARADOX, THE

Attributions of truth and falsehood under certain conditions generate the "liar paradox." The most famous illustration of this comes from the Epistle to Titus, in which

St. Paul quotes approvingly a remark attributed to Epimenides: “One of themselves, even a prophet of their own, said, The Cretans are always liars, evil beasts, slow bellies. This witness is true” (King James version). Let us suppose that Epimenides, the Cretan prophet, did say that the Cretans are always liars, and let us consider the status of his utterance—call it *E*—under the following two conditions. (1) A Cretan utterance counts as a lie if and only if it is untrue. (2) All Cretan utterances, except perhaps *E*, are untrue. Now, if *E* is true, then, since *E* is a Cretan utterance, not all Cretan utterances are untrue. Hence, Cretans are not always liars (by (1)), and so *E* must be untrue. On the other hand, if *E* is untrue, then indeed all Cretan utterances are untrue (by (2)). Hence, Cretans are always liars (by (1)), and so *E* is true after all. Both the hypotheses, that *E* is true and that *E* is not true, yield, therefore, a contradiction. Yet the steps in the argument are all apparently valid, and the initial setup is not impossible. This is the liar paradox.

The paradox was discovered by Eubulides of Miletus (fourth century BCE) and has exercised logicians down the ages to the present time. (See Bocheński 1961, Spade 1988.) For principally two reasons, interest in the paradox was especially great in the twentieth century. First, arguments similar to that found in the liar wreaked havoc in several prominent logical systems (e.g., those of Gottlob Frege and Alonzo Church). This prompted a search for systems that were immune from paradox. Second, the rise of semantical studies created a need for a better understanding of the notions of truth, reference, and the like. The notions are fundamental to semantical investigations, but the paradoxes reveal a profound gap in our understanding of them. (The notion of reference, like other semantical notions, exhibits, under certain conditions, paradoxical behavior.)

The liar and related paradoxes raise a number of difficult conceptual problems. One is the normative problem of designing paradox-free notions of truth, reference, and the like. Another is the descriptive problem of understanding the workings of our ordinary, paradox-laden notions. The work on the paradoxes in the first half of the twentieth century is, perhaps, best viewed as addressing the normative problem. The work in the second half is best viewed as addressing the descriptive problem. Some of this work is outlined below.

Let us sharpen the descriptive problem a little. For simplicity, let us restrict our attention to a fragment, *L*, of our language that contains no problematic terms other than “true.” All other terms in *L* have, let us suppose, a classical interpretation. How should “true” be inter-

preted? A natural demand is that the interpretation must validate the T-biconditionals, that is, all sentences of the form,

(T) “*B*” is true if and only if (iff) *B*,

where *B* is a sentence of *L*. The argument of the liar paradox shows, however, that every possible classical interpretation of “true” is bound to make some T-biconditionals false. (This is a version of Alfred Tarski’s indefinability theorem.) How, then, should we interpret “true”? Should we abandon the natural demand? Or the classical framework? Or the naive reading of the T-biconditionals? Essentially, the first course is followed in the contextual approach, the second in the fixed-point approach, and the third in the revision approach.

## THE CONTEXTUAL APPROACH

This approach takes “true” to be a context-sensitive term. Just as the interpretation of “fish this long” varies with contextually supplied information about length, similarly, on the contextual approach, with “true”: Its interpretation also depends upon contextual information. There is no consensus, however, on the specific information needed for interpretation. In the levels theory due to Tyler Burge and Charles Parsons, the context supplies the level at which “true” is interpreted in a Tarskian hierarchy of truth predicates. In the Austinian theory of truth developed by Jon Barwise and John Etchemendy, the relevant contextual parameter is the “portion” of the world that a proposition is about. In the singularity theory of Keith Simmons, the relevant information includes certain of the speaker’s intentions.

Contextual theories assign to each occurrence of “true” a classical interpretation, though not the same one to all occurrences. This has several characteristic consequences: (1) Occurrences of “true” do not express global truth for the entire language (by Tarski’s undefinability theorem). They express instead restricted or “quasi” notions of truth; the former possibility is realized in the levels theory, the latter in the singularity theory. (2) Truth attributions, even paradoxical ones, have a classical truth-value. Paradox is explained as arising from a subtle, unnoticed, shift in some contextual parameter. (3) Classical forms of reasoning are preserved. But caution is in order here: Whether an argument exemplifies a classically valid form turns out to be nontrivial. For example, the argument “*a* is true,  $a = b$ ; therefore, *b* is true” exemplifies a classically valid form only if “true” is interpreted uniformly, but this is nontrivial on the contextual approach.

## THE FIXED-POINT APPROACH

This approach interprets “true” nonclassically. It rests on an important observation of Saul Kripke, Robert Martin, and Peter Woodruff. Consider again the language  $L$ , and assign to “true” an arbitrary partial interpretation  $\langle U, V \rangle$ , where  $U$  is the extension and  $V$  the antiextension (i.e., the objects of which the predicate is false). We can use one of the partial-valued schemes (say, Strong Kleene) to determine the sentences of  $L$  that are true ( $U'$ ), false ( $V'$ ), and neither-true-nor-false. This semantical reflection defines a function,  $\kappa$ , on partial interpretations;  $\kappa(\langle U, V \rangle) = \langle U', V' \rangle$ . The important observation is that  $\kappa$  has a fixed point: There exist  $\langle U, V \rangle$  such that  $\kappa(\langle U, V \rangle) = \langle U, V \rangle$ .

Certain partial-valued schemes have a least fixed point, which is a particularly attractive interpretation for “true.” It is also the product of an appealing iterative construction: We begin by supposing that we are entirely ignorant of the extension and the antiextension of “true”; we set them both to be  $\emptyset$  (the null set). Despite the ignorance, we can assert some sentences and deny others. The rule “Assert ‘ $B$  is true’ for all assertible  $B$ ; assert ‘ $B$  is not true’ for all deniable  $B$ ” entitles us to a new, richer interpretation,  $\kappa(\langle \emptyset, \emptyset \rangle)$ , for “true.” But now we can assert (deny) more sentences. The rule entitles us to a yet richer interpretation  $\kappa(\kappa(\langle \emptyset, \emptyset \rangle))$ . The process, if repeated sufficiently many times, saturates at the least fixed point.

Under fixed-point interpretations, the extension of “true” consists precisely of the truths and the antiextension of falsehoods. The T-biconditionals are, therefore, validated. They are not, however, expressible in  $L$  itself: fixed points exist only when certain three-valued functions, including the relevant “iff,” are inexpressible in  $L$ .

## THE REVISION APPROACH

This approach holds truth to be a circular concept. It is motivated by the observation that truth behaves in a strikingly parallel way to concepts with circular definitions. Suppose we define  $G$  thus:

$x$  is  $G =_{\text{Df}}$   $x$  is a philosopher distinct from Plato or  
 $x$  is Plato but not  $G$ .

The definition is circular, but it does impart some meaning to  $G$ .  $G$  has, like truth, unproblematic application on a large range of objects. It applies to all philosophers distinct from Plato and fails to apply to nonphilosophers. On one object, Plato,  $G$  behaves paradoxically. If we declare Plato is  $G$ , then the definition rules that he is not  $G$ ; if we declare he is not  $G$ , the definition rules that he is

$G$ . This parallels exactly the behavior of truth in the liar paradox.

The revision account of truth rests on general theories of definitions, theories that make semantic sense of circular (and mutually interdependent) definitions. Central to these theories are the following ideas. (1) A circular definition does not, in general, determine a classical extension for the definiendum (the term defined). (2) It determines instead a rule of revision. Given a hypothesis about the extension of the definiendum  $G$ , the definition yields a revised extension for  $G$ , one consisting of objects that satisfy the definiens (the right side of the definition). (3) Repeated applications of the revision rule to arbitrary hypotheses reveal both the unproblematic and the pathological behavior of the definiendum. On the unproblematic the revision rule yields a definite and stable verdict, irrespective of the initial hypothesis. On the pathological this ideal state does not obtain.

The ingredient needed to construct a theory of truth once we have a general theory of definitions is minimal: It is just the T-biconditionals, with “iff” read as “ $=_{\text{Df}}$ .” This reading was suggested by Tarski, but, as it results in a circular definition, it can be implemented only within a general theory of definitions. Under the reading, the T-biconditionals yield a rule of revision. Repeated applications of this rule generate patterns that explain the ordinary and the pathological behavior of truth. The revision approach thus sees the liar paradox as arising from a circularity in truth. The approach has been developed by, among others, Anil Gupta, Hans Herzberger, and Nuel Belnap.

The three approaches, it should be stressed, do not exhaust the rich array of responses to the paradoxes in the twentieth century.

## LIBERALISM

By definition, a liberal is one who believes in liberty, but because different people at different times have meant different things by liberty, "liberalism" is correspondingly ambiguous. The word was first heard in a political sense in England in the early nineteenth century, when "liberals" were thus named by their Tory opponents. Indeed, they were first called *liberales*, and the Spanish form was used "with the intention of suggesting that the principles of those politicians were un-English" (see *Shorter Oxford English Dictionary*). This was ironical, since the word *liberal* had been adopted by the Spaniards for policies they regarded as essentially English—that is, the Lockean prin-

ciples of constitutional monarchy, parliamentary government, and the rights of man. In any event, the Englishmen who were called liberals (though as late as 1816 Robert Southey was still calling them *liberales*) rejoiced in the name, and what was intended to be a pejorative quickly proved to have a distinctly pleasing flavor, perhaps partly because its other significance, the Shakespearean sense of liberal as "gross" or "licentious," had given way to the modern sense of liberal as "bountiful," "generous," or "open-hearted."

## ENGLISH LIBERALISM

Traditional English liberalism has rested on a fairly simple concept of liberty—namely, that of freedom from the constraints of the state. In Thomas Hobbes's memorable phrase, "The liberties of subjects depend on the silence of the law." In general, however, English liberals have always been careful not to press this notion to anarchist extremes. They have regarded the state as a necessary institution, ensuring order and law at home, defense against foreign powers, and security of possessions—the three principles John Locke summarized as "life, liberty and property." English liberals have also maintained that the law can be used to extend the liberties of subjects insofar as the law is made to curb and limit the activities of the executive government. Thus, for example, the English laws of habeas corpus, of bail, and of police entry and arrest all constrain or restrain the executive and, in so doing, increase the freedom of the people. Some instruments of constitutional law have a similar effect.

The traditional form of English political liberalism naturally went hand in hand with the classical economic doctrine of *laissez-faire*. Toward the end of the nineteenth century, however, certain radical movements and certain English liberal theorists, such as Matthew Arnold and T. H. Green, developed, partly under foreign, left-wing influences, a different—as they claimed, a broader—concept of freedom, which was, to a large extent, to prove more popular in the twentieth century than traditional English liberalism with its economic gospel of *laissez-faire*. The central aim of this new school was utilitarian—namely, freeing men from misery and ignorance. Its exponents believed that the state must be the instrument by which this end was to be achieved. Hence, English liberal opinion entered the twentieth century in a highly paradoxical condition, urging, on the one hand, a freedom that was understood as freedom from the constraints of the state and, on the other, an enlargement of the state's power and control in order to liberate the poor from the oppressive burdens of poverty. In the political

sphere this contradiction in the liberal ideology ended in the disintegration of the British Liberal Party. With the defeat of Prime Minister Herbert Henry Asquith, a disciple of the philosopher T. H. Green and an adept at reconciling contradictions, the British Liberal Party broke into two, the right-wing, or *laissez-faire*, element joining forces with conservatism and the radical, *étatiste* element merging with socialism. Only a “rump” remained.

## FRENCH LIBERALISM

The ambiguity of the word *liberalism* is more marked in French than in any other European language. Some writers hold that as a result of events in France since the time of Louis XIV, the French people have been divided into two political camps: One that supports the Roman Catholic Church, traditional social patterns, and the Syllabus of Pius IX (1864) and one that opposes the church and favors parliament, progress, and the rights of man. Historians who see France in these terms call one side *conservateur*, the other *libéral*. Opposed to this view are those historians who see not two, but at least three, continuing traditions in French political thought: on the right, royalism and conservatism; on the left, socialism, anarchism, syndicalism, and communism; in the center, liberalism. In the first of these two analyses, *libéralisme* is understood to embrace all the creeds of the left; according to the second analysis, *libéralisme* is a political doctrine at variance with the creeds of the left.

Again, one can distinguish two distinct—indeed, opposing—schools among French theorists who claim to be liberal. One is the Lockean liberalism of Voltaire, Baron de Montesquieu, and Benjamin Constant (in effect, also that of François Guizot and the July monarchy of Louis Philippe)—the liberalism of the minimal state, individualism, and *laissez-faire*. But there is a second liberalism, represented by the masters of the French Revolution and by the youthful Napoleon Bonaparte, which is democratic, Rousseauesque, and *étatiste*. Whereas Lockean liberalism understands freedom as being left alone by the state, the other liberalism sees freedom as ruling oneself through the medium of a state that one has made one's own.

Both these schools of *libéralisme* contributed something to the ideology of the French Revolution, and the often unperceived contradiction between them may also be said to have contributed to the intellectual confusion of those times. The fall of Napoleon was the signal for a return to the more purely Lockean style of liberalism. Benjamin Constant not only insisted that Jean-Jacques Rousseau's concept of liberty was an illusory one but also

maintained that “*Du Contrat Social* [1762] so often invoked in favour of liberty, is the most formidable ally of all despotisms.” Constant and his friends desired only to reproduce in France the Lockean Glorious Revolution of 1688. In 1830 they believed they had succeeded; Louis Philippe was enthroned on the basis of an understanding very like that on which William and Mary had been crowned in England. Politicians such as Guizot, who called themselves Libéraux, were put in charge of the kingdom. The result was not inspiring. A new bourgeoisie basked in the liberty the Lockean state introduced; the great were diminished, but the poor were not elevated. A rebellion came from the left in 1848, and the right replied with Napoleon III. Henceforth, there were few self-styled Libéraux of any importance in French politics and no liberal party. When new parties were formed later in the century, the name chosen by the center was Republicain rather than Libéral. This is not to say that liberalism died in France in 1848; rather, the word *libéralisme* thereafter ceased to call to the minds of French-speaking people any clear or distinct idea.

In 1912 Émile Faguet published a celebrated work, *Le libéralisme*, in which he took a rigidly Lockean position. “The state,” he wrote, “is an evil; a lesser evil than anarchy, but nevertheless to be limited to the tasks of securing public order and safety through the judiciary, police and army.” Several critics at the time attacked Faguet's definition as being outmoded; nevertheless, the definition of *libéralisme* in the 1935 edition of the *Dictionnaire de l'Académie Française* is, like Faguet's, thoroughly Lockean; it defines *libéralisme* in terms of the citizen's right to freedom of thought and to protection from government interference in private and business affairs.

One of several French theorists who attacked Faguet's exposition of liberalism (and, by implication, the academy's definition) was Jean de Grandvilliers. “How the word ‘liberalism’ is perverted by those who treat it as synonymous with individualism!” he wrote in *Essai sur le libéralisme allemand* (1925). “We can only reply by giving the word its true meaning.” According to Grandvilliers, the true meaning of liberalism is to be found in a policy of extending the liberty of the people; he maintained that the intervention of the state is not only a useful, but also a necessary, means to achieve that end. Grandvilliers is thus a champion of the *étatiste* school of liberalism, which derived its concept of liberty from Rousseau and which argued that as long as the state belongs to the people, the enlargement of the power of the state is equally an enlargement of the power, and therefore the freedom, of its citizens.

## GERMAN LIBERALISM

The word *liberal* was first heard in Germany in 1812, going there, as it went to England, from Spain. But the last years of Napoleon's power marked the decline of one tradition of German liberalism and the beginning of a new one. For in Germany, as elsewhere, we may discern not a single doctrine of liberalism but at least two main, conflicting schools, which again may be classified as the Lockean and the *étatiste*. The older German tradition was not merely derivatively Lockean; it also had contributed much to the formulation of Locke's own thought. In the sixteenth century it was a German philosopher, Johannes Althusius, who proclaimed that sovereignty derived from the people, and it was the German *Naturrechts* school of jurists that provided the bridge between the Stoic concept of *jus naturale* and the Lockean doctrine of the rights of man. But Locke, in turn, influenced the eighteenth-century German liberals, among whom Wilhelm von Humboldt was perhaps the most conspicuous. The very title of his book *Ideen zu einem Versuch, die Grenzen der Wirksamkeit des Staates zu bestimmen* (Ideas toward an investigation to determine the proper limits of the activity of the state; 1792), reveals his preoccupation with limited sovereignty and the minimal state. In this work Humboldt argued that the function of the state is not to do good but to ward off evil, notably the evil that springs from man's disregard for his neighbors' rights. The state, he said, "must not proceed a step further than is necessary for the mutual security of citizens and protection against foreign enemies; for no other object should it impose restrictions on freedom." Eighteenth-century Germany also had several liberal economists, including Christian Kraus, who considered that Adam Smith's *Wealth of Nations* (1776) was the most important book after the Bible.

In the nineteenth century a new school of liberalism, which was first and foremost nationalistic, arose in Germany. The freedom it stood for was the freedom of Germany, and the condition of the realization of this national freedom was the unification of Germany. Thus, whereas the old Lockean liberals were against the state, the new nationalist liberals wanted to create a greater state. The French declaration of 1789 proclaimed the rights of man; the German liberals inspired in 1848 a declaration of the rights of the German people. The new German liberals thought in terms of collective, rather than individual, rights. Thus, the *étatiste* German liberals saw nothing incongruous in sending a mission in 1849 from the Frankfurt parliament to Berlin to offer the crown of all Germany to a Prussian monarch, Friedrich Wilhelm, who

detested democracy and who, in any event, grandly announced that he did not take crowns from commoners.

The difficulty of understanding in what sense this new German liberalism rested on a principle of freedom is that of understanding what it was that its votaries were demanding freedom from. Indeed, for many German liberals it was not a question of freedom from anything. German metaphysics of the same period was working out a concept of freedom that had nothing to do with resisting constraint. Guido de Ruggiero, a sympathetic Italian historian of German liberalism wrote:

The eternal glory of Kant is to have demonstrated that obedience to the moral law is freedom.... It was the great merit of [G. W. F.] Hegel to have extracted from the Kantian identification of freedom with mind, the idea of an organic development of freedom, coinciding with the organisation of society in its progressively higher and more spiritual forms.... The State, the organ of coercion *par excellence*, has become the highest expression of liberty. (*History of European Liberalism*)

The idea that true freedom is to be found in obedience to the morally perfected state gave a theoretical justification (of a highly abstract kind) to the nineteenth-century German liberals' pursuit of liberty in submission to a strong and unified nation-state. But these high-thinking theorists never recovered from Friedrich Wilhelm's snub in 1849. Germany got its unity, but it was the imperialists, not the new liberals, who achieved it, and it was Otto von Bismarck, rather than Immanuel Kant, who gave the unified nation its political ethos. After the defeat of the Nazi regime in 1945, however, there was some revival of the Lockean type of liberalism in Germany.

## AMERICAN LIBERALISM

In the United States the word *liberal* has never enjoyed the prestige it has in the United Kingdom, for in America there has never been, as there has in England, a national liberal party. The short-lived Liberal Republican Party of the 1870s was without a coherent program. Horace Greeley, its presidential candidate, was at once a socialist, spiritualist, vegetarian, and total abstainer; his personality led many Americans of his time to associate the word *liberal* with a visionary crank, and some still do. F. O. Matthiessen wrote in 1948: "In our nineteenth-century political life we had no such formulated division as that between the Conservatives and Liberals in England.... The key word seized upon by our native radical movement of the eighties and nineties, that of the Populists,

was not 'liberal' but 'progressive'" (*From the Heart of Europe*, New York, 1948, p. 90). Again, whereas in Vernon Louis Parrington's *Main Currents in American Thought* the word *liberal* occurs on almost every page, Parrington's pupil Henry Steele Commager never once uses the words *liberal* and *liberalism* in his continuation volume, *The American Mind* (New Haven, CT, 1950).

Just as in France the word *liberal* had been used by some writers for almost any kind of left-wing opinion, so in America the word *liberal* was widely adopted after the Great Depression as a soubriquet for "socialist." In *The Liberal Imagination*, Lionel Trilling defined liberalism as meaning, among other things, "a belief in planning and international co-operation, especially where Russia is in question." This definition may not have been wholly authorized by common usage, but there can be no doubt that the word *liberal* has come to be associated in the American public's mind with *étatiste* and left-wing ideologies rather than with the Lockean notions of *laissez-faire* and mistrust of organized power.

Indeed, it was one of Parrington's arguments in *Main Currents in American Thought* that American liberalism, as he called it, had always been concerned with democracy in a way that Locke and his English followers had not. Yet even before the emergence of twentieth-century left-wing liberalism, two rival creeds, both of which could reasonably be called liberal, contended for political supremacy. The first, as Parrington pointed out, was close to the "English philosophy of *laissez-faire*, based on the assured universality of the acquisitive instinct and postulating a social order answering the needs of the abstract 'economic man' in which the state should function in the interests of trade." The second liberalism was Rousseauesque rather than Lockean. It was "based on the conception of human perfectibility" and looked toward an egalitarian democracy "in which the political state should function as the servant to the common well-being."

The dominant political sentiment of the American tradition derives something from both these kinds of liberalism, for it has combined a Lockean attachment to liberty from the state with a Rousseauesque belief in democracy and equality. Nevertheless, perhaps it is still not quite respectable to be an avowed liberal in America. This may be partly because there has been no traditional support for a liberal party. It is also partly because not only socialists, but also communists and communist sympathizers, have not ceased to assume the title "liberal" rather than a more explicit expression of their political commitment.

A remarkable variety of political structures has been thought by different philosophers to embody liberty, and a correspondingly mixed company has shared the name "liberal." In singling out certain main streams or schools of liberal thought, one has to be mindful of the divergences that exist even among those which can be usefully grouped together. One might broadly divide philosophers of freedom into those who think that to be free is to be able to do what one wants to do and those who think that to be free is to do what one ought to do. By a similar method, one might divide liberals into those who see freedom as something that belongs to the individual, to be defended against the encroachments of the state, and those who see freedom as something which belongs to society and which the state, as the central instrument of social betterment, can be made to enlarge and improve. It remains to be said that some of the greatest names in the history of liberal thought, including John Stuart Mill himself, are strangely poised between these two positions.

## LIBERALISM [ADDENDUM]

The theory of liberalism and political philosophy in general were dramatically revitalized by the publication of John Rawls's *A Theory of Justice* (1971). In that work Rawls adopts the social contract model of political theory but with several key innovations. Rawls states that his theory seeks to capture the essence of the social contract theories of Locke, Rousseau, and Kant and develop the core idea of the contract to deal with traditional criticisms of the contract model of political legitimacy. The social contract model of justifying political authority has as its core idea that the basic principles of justice are the object of an original agreement that free and rational persons concerned to further their own interests would accept in an initial position of equality.

### THE ORIGINAL POSITION

For Rawls, the first question for political theory is to specify what initial conditions are right for deciding the question of justice. His answer is what he calls the "original position," a hypothetical state of nature or situation without a government designed to be the conceptual context within which the basic principles of justice will be considered and the main outlines of the distribution of rights and duties will be defined and agreed upon. Rawls sees the original position as a heuristic device or a thought experiment used to rethink and clarify our intuitions

about what justice is and what the basic structure of a just society would consist in. Rawls's concept of the original position has the following important components: the "veil of ignorance"; definition of the "people" in the original position; and, general knowledge that includes knowledge of the circumstances of justice and knowledge of the main competing theories of justice.

The overall design of the original position is based on what Rawls calls "considered judgments." These are judgments where moral capacities are likely to be manifested without distortion or prejudice. These judgments, for example, would include the beliefs that slavery, religious intolerance, and racism are wrong and ideas about fairness and human equality. Rawls terms his understanding of justification in ethics "reflective equilibrium." This model of justification rejects traditional foundationalist ideas of justification that hold that there are self-evident ethical principles from which one can derive specific moral rules and principles of justice and accepts a more coherentist model of justification. This coherence paradigm of justification holds that a theory is justified if one's considered judgments and moral and political principles cohere in a consistent belief system. By "equilibrium" Rawls means that one's judgments and principles are compatible and by "reflective" he means that one is fully and rationally aware of what our judgments and principles are and their derivation.

The veil of ignorance is a central feature of the original position. This imaginary veil is necessary, Rawls argues, because it excludes information that is not morally relevant or is a product of factors that are unjust and could be a source of prejudice. This means that information about one's social class, wealth, sex, race, abilities, personality, intelligence, particular conception of the good, health and the specific circumstances of one's society are excluded.

Though members of the original position are not allowed specific information about themselves, they are allowed certain general information. Members of the original position consider themselves free, equal, rational, and self-interested. As free, Rawls means no one is under the authority of another and as equal he means each has the same rights to make choices and decisions. As rational, Rawls means that people understand the ideas of justifying beliefs with evidence and that one should choose the most appropriate means to achieve one's goals. As self-interested, Rawls does not mean that people in the original position are selfish but rather that they are interested in their own welfare.

Members of the original position know that they need what Rawls calls “primary goods”; namely, certain basic rights, liberties, opportunities, income, wealth, and self-respect. These Rawls considers necessary means for whatever goals one may have and as such provide the motivation element in the deliberation in the original position.

Participants in the original position are also allowed knowledge of the circumstances of justice and the main competing theories of justice. The circumstances of justice include the notion that individuals coexist with roughly equal physical and mental powers, but are morally and intellectually limited with similar needs but different life goals in a world of moderate scarcity of resources.

The main competing theories of justice the members of the original position focus on are that of Rawls’s theory, which he will call “justice as fairness,” and utilitarianism. Rawls claims that people of the original position would reject utility as the principle of justice because, according to Rawls, the theory may allow injustice to a few to maximize utility overall.

Given his characterization of the hypothetical choice situation, Rawls believes members of the original position would agree to two principles of justice. Rawls’s first principle states: “Each person is to have an equal right to the most extensive basic liberty compatible with a similar liberty for others” (1971, p. 60). The second principle holds: “Social and economic inequalities are to be arranged so that they are both, a) reasonably expected to be to everyone’s advantage, and b) attached to positions and offices open to all” (1971, p. 60). According to Rawls, members of the original position would also decide that the first principle has priority over the second and cannot be sacrificed to realize the second principle more fully.

The first part of the second principle Rawls calls the “difference principle,” and it requires that all inequality in economic matters benefit all members of society, especially the least advantaged. The second part of the second principle requires what Rawls calls “fair equality of opportunity.” Fair equality of opportunity requires not only that there are no legal obstacles for any position in society, but it would also provide for equal starting social conditions for all. Rawls believes that all people should have an equal chance to achieve any position in society regardless of what their family background, their social class, sex, religion, and ethnic background happen to be. Government would have to make sure that people have such equal opportunity by providing an equally good

education and other services intended to prevent great social inequality in income, opportunity, and wealth.

Rawls admits that to implement his two principles may mean a large role for government, but he does not demand that either socialism or capitalism would necessarily be agreed upon in the original position. He considers this an empirical decision that social conditions and economic efficiencies would dictate.

Rawls’s theory has been praised and critiqued. Many applauded its robust defense of welfare liberalism, concern for the poor, and the central importance of fair equality of opportunity. Others were pleased by the interdisciplinary nature of Rawls’s work and a style accessible to the ordinary educated person.

### CRITICISMS OF RAWLS’S THEORY

Critics of Rawls’s theory come from the political right and left. Those on the right feel he overemphasizes equality and puts too much power in the hands of government. Libertarians such as Robert Nozick (1974) claimed he has reduced liberty too greatly at the expense of equality and allowed for the violation of the right to property by allowing increased taxation of the rich to help the poor.

Critics of Rawls from the left believe he has allowed too much inequality. Socialists believe that Rawls should have realized that capitalism allows too much power in the hands of the capitalists who would control government to promote their interests. Marxists also claimed Rawls’s theory of human nature is biased in favor of human nature as it exists in an alienated form under capitalism based on competitive individualism and overlooking the great power of social class in limiting freedom. Other critics such as James Sterba (2004) have questioned certain specific elements of the theory. Sterba claims the difference principle would in fact not be chosen in the original position. Sterba argues that members of the original position would choose a guaranteed minimum rather than the difference principle, but Sterba then extends that minimum to distant peoples and future generations which, he believes, will have the effect of greater equality.

Still other critics such as Michael Sandel (1982) believe that liberal philosophers such as Rawls place too much emphasis on individual rights and not enough on the role of the community and individual responsibility.

### RAWLS’S LATER WORK

Rawls’s later work, *Political Liberalism* (1993), still defends his principles of justice but also attempts to

address some of the criticisms of his earlier work. The goals of *A Theory of Justice* (1971) were, according to Rawls, to develop justice as fairness as a superior moral and political theory to utilitarianism and use the social contract model to do so. The problem with these goals, Rawls explains in *Political Liberalism*, is that he was endorsing a comprehensive doctrine similar to Kantianism that is problematic in a world of incompatible doctrines none of which can be rationally determined to be correct. A “comprehensive doctrine” is defined by Rawls as a doctrine that encompasses all central values and beliefs about life. In this sense the main world religions and philosophical systems such as utilitarianism are comprehensive doctrines. By contrast, a “political conception” is a set of ideas that applies only to the political realm and does not assume any comprehensive doctrine but rather uses ideas found in the political culture of a society.

As Rawls puts it, the problem for his theory and political philosophy in general is: “How is it possible that there may exist over time a stable and just society of free and equal citizens profoundly divided by reasonable though incompatible religious, philosophical and moral doctrines?” (1993, p. xviii). Rawls hopes to solve this problem of reasonable pluralism of comprehensive doctrines by establishing the following: (1) to distinguish more clearly the difference between a comprehensive doctrine from a political one; (2) to emphasize the importance of stability in a well-ordered society in a world of reasonable pluralism of comprehensive doctrines; (3) to clarify that justice as fairness is not a comprehensive but a political doctrine; and (4) to show that political liberalism assumes and is compatible with a pluralism of reasonable comprehensive doctrines.

The idea of a well-ordered society is central to Rawls’s answer to the problem of pluralism. For Rawls, well-ordered society is a stable society that, when realized, generates its own support from the citizenry being accepted as a fair system of cooperation based on publicly recognized rules agreed by all as just. A well-ordered society must also be one where the conception agreed to is limited to the political because of three facts. First, there is what Rawls calls the diversity of reasonable comprehensive religious, philosophical, and moral doctrines found in modern societies. The second fact is that to maintain one comprehensive doctrine as the correct one would entail the use of coercive physical state power. Third, a secure democratic government must be freely supported by at least a majority of its citizens.

Rawls believes a well-ordered society is possible because there is a limited agreement about political jus-

tice in the political culture of democratic societies. This agreement he calls an “overlapping consensus.” This consensus is not a mere “modus vivendi” according to Rawls; that is, it is not merely the result of negotiation of self-interested parties, but rather it is agreed to on moral grounds found in the differing comprehensive doctrines. As such, Rawls calls his political theory of liberalism “freestanding” in that it is not based on any comprehensive doctrine.

On the one hand, many philosophers praised *Political Liberalism* as a major work dealing with the postmodern world of pluralism and ideological diversity. Critics, on the other hand, claimed that Rawls has merely assumed an overlapping consensus among comprehensive theories when in fact there is no such consensus. Others prefer his earlier work because they feel there is a need for some foundations to justify the theory that seems to be lacking in the new presentation.

Discussion of Rawls’s work continues, but there is a growing consensus that his contributions to the field of political theory of liberalism will stand as a major addition to the canon of political philosophy for a long time to come.

## LIBERATION IN INDIAN PHILOSOPHY

The concept of liberation presupposes someone's state of bondage and anticipates the possibility of his or her release into a state of freedom. From the philosophical perspective bondage marks the human predicament of leading a precarious existence in an unstable world. In Indian philosophy the state of bondage is termed *saṃsāra* (global flow) and understood as a beginningless process of life of beings who are born, die, and are constantly reborn. This process is governed by the eternal law called in mainstream Hinduism *sanātana dharma*. This expression is *multivalent*, having several layers of meaning; Indian thinkers regard it as a matrix encompassing reality in its totality. In Buddhism *dharma* occurs without the attribute "everlasting," but is understood as being beyond time.

The multivalency of *sanātana dharma* gives it at least three meanings. First, as the eternal law it represents an impersonal force inherent in everything so that reality is orderly rather than chaotic; processes of reality follow the law of cause and effect. Second, the aspect of timelessness of *dharma* implies the view that even the phenomenal reality has no conceivable beginning and end, but keeps renewing itself in cycles. In other words, the global world process—including the present universe—has no fixed origin, such as a creative act of God, and will never come to an end to be replaced by the eternal "new earth and new heaven" after a day of judgment. Rather, it undergoes periodic renewals: At the beginning of each period the world process starts with the emergence (*śṛṣṭi*) of the universe from its hidden dimension into the state of manifestation; in the course of its duration (*sthiti*) it evolves to a peak, followed by decline and end in universal dissolution into the unmanifest state (*pralaya*) called cosmic night. After a period of latency, the whole process starts again.

The lives of individual beings proceed within this global framework from birth to adulthood, old age, death and rebirth in a never-ending round of *saṃsāric* exist-

tences. During the cosmic night they subsist in a kind of limbo or oblivion. Third, the concept of *dharma* also refers to the timeless and absolute reality beyond the manifested one; it represents the final goal of religious and philosophical quest equated with the ultimate truth. This truth is eternal, outside time, and independent of the changeable phases of the phenomenal reality manifested within time. The manifestation of the eternal truth or law within the universe dominated by time does not make the world everlasting in the sense of a lineal duration, but provides for its cyclic nature, its recurring rise and fall.

The concept of *dharma* understood as the absolute truth and ultimate reality has still another connotation—that of consciousness, awareness, or intelligence. Truth makes sense only if it is known. Indian philosophy, unlike Western science, has never conceived of reality without consciousness. Thus, a verse in one of the earliest Indian philosophical texts (1500–1000 BCE), the creation hymn of the *Ṛg Veda* (10, 129, 4), describes the primordial oneness (*tad ekam*) as experiencing desire (*kāma*), the earliest seed of its mind (*manaso retaḥ*), which led to manifestation. The dimension of consciousness as an inherent quality of reality in its ultimate state evokes two fundamental insights. First, the idea of the ultimate personality (*puruṣottama*), albeit an infinite one, conceived as the personality of God, the free agent behind the world process, although not an omnipotent one. Second, it suggests that the individual human consciousness, being an instance of the universal dimension of consciousness, has—despite its present limitations—the potential of grasping reality on the ultimate level: Man has the capability to develop an understanding and vision of the absolute truth. Extricating himself thus from the conditionality of his phenomenal existence and attaining final liberation (*mokṣa*, *mukti*), he enters the timeless dimension of the absolute without having to participate in the world process and undergo repeated incarnations.

While in bondage, he is governed by *sanātana dharma* in all its aspects. Its aspect of causality operates in human life on a higher level as the law of karma, which is much more complicated than the law of cause and effect in the material universe, yet it can be expressed in the simple saying "as you have sown, so you will reap." Every volitional act in thought, speech, or deed generates a force that produces sooner or later—in one's present life or some future existence—results that shape one's external circumstances and appearance, forming one's character and determining one's fortune. The aspect of timelessness of *dharma* makes the lives of individual beings in the sequence of reincarnations appear to be without a con-

ceivable beginning and end. However, the aspect of *dharma* as the timeless and absolute reality beyond the manifested world lends individual beings an affinity with the ultimate truth and the potentiality of realizing it by direct conscious experience, which brings about the termination of their bondage and the attainment of liberation outside time.

This necessitates entering a spiritual path, a training to deepen one's perception of reality up to the point of the final vision. Volitional input is essential for this purpose—as it is also within the karmic process to sow only wholesome deeds to earn future good results. The spiritual path was eventually systematized and became known as yoga.

The previous outline is valid in principle for all schools of Indian philosophy, including the earlier phases of Indian thought before the formation of philosophical systems. Despite the difference in terminology and sophistication of language, the ideas occur even in the oldest strata of Vedic scriptures in mythological guise, although nineteenth-century pioneers of Vedic scholarship failed to recognize them.

## THE VEDAS AND UPANIṢADS

The *R̥g Veda* uses the verb *muc* (hence *mokṣa* and *mukti*) in the creation myth when the god Indra periodically liberates the cosmic waters (= creative forces) from the clutches of the demon Vṛtra (10, 104, 9; 1, 32, 11; 4, 22, 7), thereby enabling the manifestation of the universe. As to humans, they are subjected to successive lives (*anūcīnā jīvītā*, 4, 54, 2), so liberation for them means being granted immortality (*amṛta*, *amṛtatva*). It is therefore ardently prayed for: “Lead us to immortality!” (5, 55, 4) “May I be released from death, not reft of immortality!” (7, 59, 12) “Place me in that deathless, undecaying world ... make me immortal” (9, 113, 7–11). Certain “long-haired ascetics” (*keśins*) even claimed to have won immortality during their lifetime: “Due to our sagehood we have mounted upon the winds, only our bodies do you mortals see” (10, 136, 3). The pleas for immortality show that everlasting life was not automatically granted even if one reached heaven as a result of good deeds (10, 14, 8) and religious fervor (*tapas*, 10, 54, 2). Repeated death (*punarmṛtyu*) lurked even there as is later asserted by Śatapatha Brāhmaṇa (10, 4, 3, 10), so the search for immortality continues.

The ideas of rebirth under cosmic law and liberation from it are subsequently clearly spelled out in the oldest Upaniṣads (700–600 BCE): “One becomes pure by pure actions, bad by bad ones” (Bṛhadāraṇyaka Upaniṣad 3, 2,

13), and when one dies, knowledge (*vidyā*), deeds (*karmāṇi*), and previous experience (*pūrva prajñā*) follow one (4, 4, 2). One may live in higher worlds while the merits of one's actions last, but eventually returns to this world (4, 4, 4–6). But one has affinity with the Ultimate; one's inner self (*ātman*) is, at bottom, identical with the core of reality (*brahman*, 4, 4, 5). When one realizes it and can proclaim “I am *brahman*,” one becomes the self of everything, including gods (1, 4, 10), and is freed from reincarnation. Thus, liberation is the result of the direct knowledge of one's inmost self and thereby of the inner essence of everything else brought about by meditational effort (*dhyāna*) and by renouncing external desires. Later Upaniṣads started developing methods of acquiring the liberating knowledge, thus foreshadowing the classical system of Yoga.

Two schools of thought and practice outside the Vedic tradition, Jainism and Buddhism, also systematized the path. Both emerged from the circles of wanderers (*śramaṇas*) striving for liberation from the round of rebirths by asceticism. In contrast to the Brahmanic tradition, they regarded the state of liberation as beyond description and used the negative term *nirvāṇa* (blowing-out) for it.

## JAINISM

The term used in the teachings of Jina Mahāvīra (599–467 BCE) for individual beings is *jīva* (animate substance, soul, spirit-monad) or *ātman*. In its pure form a *jīva* is perfect, omniscient, eternal, and formless and enjoys unlimited energy and infinite bliss. When he succumbs to the influx (*āśrava*) of passions (*kaṣāya*) from the phenomenal world of modalities (*saṃsāra*), the *jīva* takes shape, assuming a body born from his actions (*karmaṇa-śarīra*), and he loses his perfection and becomes a mundane pilgrim (*saṃsāri*) through innumerable forms of life whose quality is determined by the ethical quality of his actions. Good actions secure his temporary well-being in *saṃsāra*, but do not lead to liberation. Of bad actions injury to life is the most detrimental one. Liberation (*mokṣa*, *mukti*, *nirvṛti*) is achieved by purging off (*nirjarā*) of karmic burdens accumulated by past actions and stopping (*saṃvara*) further influxes by renunciation so that the soul rises above involvement in any actions. In the last stages of ascetic practice (*tapas*), the abstention from action may involve stopping even intake of food and drink; liberation is reached on the point of death by starvation. If the *saṃsāri* achieves liberation before death, he becomes a perfect one (*siddha*) or a *tīrthaṅkara* (ford-maker, the teacher of others). Discarnate *siddhas* in *nir-*

*vāṇa* enjoy four infinite accomplishments: knowledge, vision, strength, and bliss. The Jain elaborate path to liberation shows overlaps with the Buddhist one and with Patañjali's Yoga.

## BUDDHISM

Early Buddhist sources largely abstain from conceptual descriptions of the nature of beings, liberation, and ultimate reality. The Buddha (563–483 BCE) of the Pāli Canon maintained noble silence about such issues and focused pragmatically on analysis of the existential situation of man as it is accessible to everybody's experience and on practical procedures for gaining liberation and direct knowledge of true reality; called awakening or enlightenment (*bodhi*), this achievement does not include omniscience as in Jainism. Man's experience of himself is described in terms of five constituent groups of clinging (*upādānakkhandhas*):

- (1) Bodily awareness or the experience of having a form (*rūpa*)
- (2) Feelings (*vedanā*) that are pleasant, unpleasant, or neutral
- (3) Perception (*saññā*) experienced through six channels—the five senses and the mind, the latter having the function of coordinating the fivefold sensory data into conceptually grasped objects
- (4) Inner volitional dynamism described as the group of mental coefficients (*saṅkhāras*), such as instincts, urges, desires, wishes, decisions, and aspirations
- (5) Consciousness (*viññāṇa*) or the direct awareness of being conscious of visual and other sensory objects and of mental images and concepts

None of these constituents represents the inner core, substance, or soul (*atta/ātman*) of the personality—they are *anatta*—and no such core is either postulated or denied. The structural unity of the personality is expressed by the term *nāmarūpa* (name and form), occasionally also *puggala* (Sanskrit: *pudgala*) or *purisa* (Sanskrit: *puruṣa*); its constituents constantly change, yet its individuality is preserved by its continuity as a process: The Buddha frequently referred to his and others' past lives.

Bondage to the round of births and deaths governed by the laws of karma results from ignorance (*avidyā*, *moha*) of the true nature of reality (*dhamma*). Beings are then subject to craving (*taṇhā*, *lobha*) directed to fleeting and basically substanceless pleasurable experiences and develop hate (*dosa*) if somebody obstructs their aims. The

beginning of the individuals' *samsāric* sojourn cannot be found, but liberation is possible when beings realize its unsatisfactoriness, recognize desire as its cause, understand that renouncing desire will free them from rebirth, and embark on the path toward that final goal.

This is the gist of the Buddha's "four noble truths," the fourth one being the eightfold path of systematic training, the first comprehensive formulation of a liberating technique. On reaching liberation a Buddha's disciple becomes an *arahat* (worthy one) and is equal to the Buddha in the acquired state of freedom, while the Buddha surpasses him in wisdom, thus enabling him to be the "teacher of gods and men." Individuals who attain liberation on their own without the guidance of a buddha become solitary enlightened ones (*paccekabuddhas*), who do not assume a teaching mission. Early Buddhism does not admit descriptions of or speculation about the state of a liberated one (*tathāgata*) after death. Here, too, the Buddha maintains "noble silence," expressly denying only the validity of the four alternatives put to him by questioners, namely that he "is," "is not," "both is and is not," and "neither is nor is not." "The final truth (*dhamma*) is deep, unfathomable, understood only by the wise" (Majjhima Nikāya 72)—an Enlightened One.

Despite this injunction, speculation did not cease and some Hīnayāna schools of thought, including Theravāda, interpreted the Buddha's description of personality factors (*khandhas*) as unsubstantial (*anatta*) to mean denial of an inner core or any other feature that would lend individuals identity in successive lives and continuity into *nirvāṇa*. This was challenged by the Pudgalavāda school, which maintained that personality (*pudgala*) as such is as equally undefinable as *tathāgata* and that it is independent of the individual's status, whether bound or liberated, which means that it persists throughout successive lives and into *nirvāṇa*. This doctrine was adopted by many sects and remained influential for centuries.

Mahāyāna schools of thought do not appear to have had problems with personal continuity. Innumerable *tathāgatas* are active from within their spheres of influence (*buddhakṣetras*), helping beings to liberation, assisted by *bodhisattvas*, individuals developing ten perfections (*pāramitās*) on the path to buddhahood that proceeds through ten stages (*bhūmis*). Some *bodhisattvas* vow not to enter final *nirvāṇa* until all beings are liberated "down to the last blade of grass," an innovation that envisages universal liberation. This is viewed as possible on the basis of the philosophy of emptiness (*sūnyavāda*), which developed as a result of meditational experience: The mind, emptied of all contents derived from sensory

perception and conceptual activity, can make the final breakthrough into *nirvāṇa*, which is equally empty because it is inaccessible to sensory perception and undefinable. Thus, emptiness (*śūnyatā*) came to be regarded as underlying both *saṃsāra* and *nirvāṇa*, making them, at bottom, identical. Liberation occurs by shifting one's perspective.

Such tendencies to hypostatize *śūnyatā* were checked by Nāgārjuna (flourished c. 150–250), the protagonist of the Mādhyamaka school, who used the dialectical method to refute conflicting theses; truth lay in the middle, but beyond dialectics. It is accessible only to direct vision—as the Buddha taught. Tendencies to hypostatization appeared also in the Vijñānavāda school, which regards pure consciousness as the basis for not only *saṃsāra* but also *nirvāṇa*, since its achievement cannot be a conscious experience. *Saṃsāric* phenomena are mental constructs projected from the universal storehouse consciousness (*ālaya-vijñāna*), yet the emptiness and purity of the root consciousness (*mūla-vijñāna*) and of a liberated one's consciousness remain unaffected.

## HINDU SYSTEMS OF PHILOSOPHY

During the golden age of Indian civilization under the Gupta dynasty (320–510), philosophical discussions flourished between various schools of thought. Six of them came to be recognized as valid Hindu angles of viewing (*dṛṣṭi*, hence *darśana*) of reality and were systematized. All accept the basic teaching about *saṃsāric* bondage and the desirability of liberation, but differ in ontological conceptions and methodical approaches.

(1) Pūrva-Mīmāṃsā (original elucidation) regards the Vedas as eternal and pursues the path of ritual action (*karma-mārga*), which parallels cosmic processes and terrestrial events governed by the inherent law of *ṛta* (the Vedic equivalent of *dharma*), which is independent of any divine agency. Right rituals achieve anything, including rebirth in the highest existential spheres and liberation, although in advanced stages of the path ritual is interiorized and becomes a process of meditation.

(2) Vaiśeṣika (discrimination) is a kind of natural philosophy focusing on classifying reality into categories (*padārthas*). Reality is subjected to the invisible law (*adr̥ṣṭa dharma*) operating also in the ethical sphere independently of God (*īśvara*), an eternally free, omniscient spirit (not a creator) who can assist beings on the path of knowledge (*jñāna-mārga*)

based on a meditational analysis of *saṃsāric* categories that leads to liberation from them.

(3) Nyāya (guidance) analyses logical and epistemological processes that supply beings with their picture of the world. In testing its validity, Nyāya thinkers discovered syllogism that, however, required verification by experience. Logical analysis is the start of the path of knowledge (*jñāna-mārga*). It sharpens the mind, preparing it for meditational viewing, which culminates in direct knowledge of the final truth equaling liberation.

(4) Sāṅkhya (enumeration) is a dualistic metaphysical system with no God. It recognizes an infinite number of originally pure and free eternal spirits (*puruṣas*) and the creative force of nature (*prakṛti*), which conjures up the world process for *puruṣas*. As they show interest in this spectacle, *prakṛti* creates for them bodies with senses and mental functions. The *puruṣas*, fascinated by the antics of *prakṛti*, identify with their *prakṛtic* personalities and forget their true status. When a *puruṣa* recognizes this bondage, he can liberate himself by mentally discriminating between *prakṛtic* evolutes and his original pure consciousness; this is a variety of *jñāna-mārga*. His worldly personality dissolves and he regains total freedom in isolation (*kaivalya*) from *prakṛti*.

(5) Yoga (union) as one of the six *darśanas* is chiefly a systematic eightfold path to liberation called classical Yoga, expounded by Patañjali (second century BCE). However, chapter 4 of his *Yoga Sūtras* shows that it had been a philosophical system in its own right before its ontology was overshadowed by Sāṅkhya. Still, it retained the notion of God (*īśvara*), an eternally free *puruṣa* who may assist other *puruṣas* (entangled in *saṃsāra*) struggling for liberation but is neither the Creator nor the focus of a religious cult. The discipline of the Yoga path aims at experiencing liberation as autonomy (*kaivalya*) from limiting forms of existence, accompanied by the final vision of or cognitive unification with the totality of truth (*dharmamegha-samādhi*).

(6) Uttara Mīmāṃsā (higher elucidation) or Vedānta (end of Veda, meaning Upaniṣads, its base) split into three subschools. In the Advaita (nondualistic) Vedānta of Śankara (700?–750?) *brahman*, the Upaniṣadic source and core of the manifested universe, is regarded as the sole reality; the individual bondage in *saṃsāra* is an illusion (*māyā*). Liberation is achieved when this illusion is dispersed by treading

the path of knowledge (*jñāna-yoga*) that culminates in *samādhi* experienced as the unity of being, consciousness, and bliss (*sat-cit-ānanda*). The liberated one realizes that he is and has always been *brahman* and that nothing else really exists. The Viśiṣṭa Advaita (qualified nondualistic) Vedānta of Rāmānuja (c. 1077–1137) interprets the Upaniṣadic *brahman* as the eternal God who created the world out of his own subtle body by transforming it into a gross one. Beings are attributes of God, but possess their own self-conscious existence. They retain it even when liberated in mystic union with God accomplished with his grace (*prasāda*) after surrendering to him on the path of devotion (*bhakti-mārga*). Upaniṣadic passages with traces of a dualistic worldview (foreshadowing Sāṅkhya) enabled even the Dvaita (dualistic) Vedānta of Madhva (c. 1199–c. 1278) to claim Vedic authority for its interpretation. It accepts the eternal existence of *prakṛti* and the plurality of *jīvas*, who retain their individuality even in the state of liberation granted as God's grace to those who live pure lives and embrace *bhakti-mārga*. Others may transmigrate in *saṃsāra* forever. Some evildoers may even reach a point past redemption and face eternal damnation in infinite remoteness from God.

A modern approach to liberation appears in the writings of Aurobindo (1872–1950). He envisioned a new phase in the world's evolution: if enough individuals prepare themselves through yoga for receiving the cosmic consciousness, then they could bring about the spiritualization of the earth or even the whole universe. This idea of universal liberation has its origin in the vow of Mahāyāna *bodhisattvas* to liberate all beings “down to the last blade of grass.”

## LIBERATION THEOLOGY

Liberation theology is the name of a movement that arose in the churches, both Catholic and Protestant, of Latin America during the last third of the twentieth century. It also describes a theological trend that is found, often under different names and with somewhat different emphases across the world, as black theology in the United States and South Africa, as Dalit theology in India, as Minjung theology in Korea, and elsewhere in other forms.

### THEOLOGY

The earliest and still definitive statement of the movement is *A Theology of Liberation: History Politics, and Salvation* (1988) by Gustavo Gutiérrez. The basic principles it sets forth are:

- (1) Theology is critical reflection on Christian praxis. Faith, charity, and commitment to God and to others in the struggle for humanity and justice are primary. Theology relates this praxis to the sources of revelation and the history of the church.
- (2) Biblical revelation commits the church to God's "preferential option for the poor." The poor are, by their condition, involved in a struggle to realize their humanity and to become "subjects of their own history," against the political, economic, and social powers that marginalize and oppress them. This struggle is revolutionary, not reformist. The church belongs

with the poor in the midst of it, doing theology in a revolutionary situation.

- (3) The struggle of the poor for social justice is a work of human self-creation that finds its source, meaning, and hope in God's work. Salvation history is at the heart of human history, in creation, covenant, Christ's incarnation, and the coming kingdom of God. Political liberation is a partial salvific event, a historical realization of the kingdom, that looks forward to its ultimate fulfillment by divine grace operating in the human struggle, informing its character and directing it toward ever larger goals of human community.

This is still its basic structure. In its development and spread, however, three major issues have arisen.

### CRITIQUE: DEFINING THE POOR

First, how are the poor defined? The Latin American theologians clearly have a dependent economic class in mind, created by exploiting landlords, industrialists, and bankers, along with their political and military agents. This definition, in terms of the dehumanizing dynamics of the capitalist system and class struggle against it, clearly borrows from Karl Marx. José Miguez Bonino (1976) acknowledges this explicitly as do many others. The Vatican, though affirming a preferential option for the poor, has been severely critical of this tendency to identify the poor of scripture with the proletariat that Marx defined. Liberation theologians claim, however, that this analysis is the secular expression in modern industrial society of a theme in Christian history that finds its source in the Hebrew prophets and the incarnation of Christ: the saving work of God liberating the people from the economic and political power of organized human sin. *The Kairos Document, Challenge to the Church: A Theological Comment on the Political Crisis in South Africa*—(1986), without appealing to Marx, makes the same argument concerning the apartheid system, calling it prophetic theology, as opposed to (a) state theology, which justifies the status quo, and (b) church theology, which is cautiously critical but without social analysis or a strategy for revolutionary change. Minjung theology in Korea focuses on a politically oppressed people (minjung), given hope by biblical history and promise, to strive for their liberation in a messianic kingdom where Jesus the suffering servant is lord. For Dalit theology in India, like American black theology, it is a subjugated minority, the outcastes (the dalits), to which the promise of God comes, in their conflict with an oppressive majority. Black theology draws especially on the Exodus of the

Israelites from Egypt to legitimate black people's fight for freedom.

All these movements agree that liberation is the basic theme of the Christian message. All see political, economic, cultural, and even religious powers as the instruments of oppression against which they struggle in God's name. They differ in their perception of how the poor are defined and which powers are their primary antagonists. The power analysis that Marxism provides is determinative for some and secondary for others. All of them, however, incorporate it into a more subtle and insightful guide that scripture provides to Christian understanding of the poor and to action that will realize God's promise.

### CRITIQUE: THE QUESTION OF TRUTH

Second, how is the truth claim of liberation theology validated? This question arises on two levels. First, the hermeneutic of suspicion, which probes the roots of all truth claims in social experience and defines theology as a reflection on social praxis, owes much to Marx. It contradicts the teaching of St. Thomas Aquinas about the universality of reason and natural law as perfected, not destroyed by revelation. It reflects, however, the reformation understanding of reason distorted by human sin and is rooted, liberation theologians would claim, in the way God is known in the biblical history of calling, covenant, and promise.

The question remains, then, how divine revelation corrects and redeems the self-understanding also of the poor. How is truth, beyond the interests of one social group, known? Juan Luis Segundo (1976) describes the process as an expanding hermeneutical circle. Experience of reality from the perspective of the poor leads to ideological suspicion toward received structures of authority, morals, and dogma. This leads to a new awareness of God, which in turn creates a new hermeneutic for interpreting the biblical story. One does not escape ideology through this circle. But biblical revelation at one pole and the human condition of the poor at the other direct and correct it toward political and spiritual liberation. Paulo Freire develops the same line of thought as a teaching method in *Pedagogy of the Oppressed* (1970), with its emphasis on learning to be human in Christian-base communities through defining and struggling against oppressive powers while being transformed by God's saving love in the struggle.

### CRITIQUE: SIN AND HOPE

Third, is liberation theology a universal message that offers hope to all, or a theology of and for the oppressed

only? Vatican critiques, primarily in Pope John Paul II's speech to the Latin American bishops at the 1979 Puebla Conference in Mexico and in two "Instructions" from the Congregation for the Doctrine of the Faith 1984 and 1986, were especially strong on this point. (cf. A.T. Hennelly, *Liberation Theology: A Documentary History*, 1990). Authoritative for theology is not contemporary social analysis but the truth of the saving gospel of Christ revealed in scripture and interpreted by church tradition. The human situation must be understood in the light of the experience of the church through the ages as it responds in faith to God and the world. In this context one understands that the basic bondage is not just political oppression, but slavery to sin in all forms, that preferential option for the poor is concern for all who are caught in this bond, and that Jesus's transforming, peacemaking, pardoning and reconciling love is the true liberation. Therefore, the church cannot sanction the violence of class war. It cannot identify God with historical achievement. It cannot understand freedom only as political.

### REPLIES TO CRITICS

To these and to other criticisms, also from Protestant sources, liberation theologians reply variously. In replying to critics in his introduction to the revised edition (1988) of *A Theology of Liberation* Gutiérrez clearly addresses the community of the whole church with a call to join the poor in their struggle for liberation, confident of the reign of God, which is for all. Liberation, he says, is salvation on three levels: freedom from economic and political oppression, personal transformation, and ultimately redemption from sin. It is a movement with both historical and eschatological dimensions. However, his view of the church is less hierarchical and institutional than the Vatican critique. His emphasis on praxis as response to faith is also more social and historical.

Others, in their contexts, deal with the question in various ways. The *Kairos Document* calls the church to struggle against tyranny with appropriate force, with the hope that the coming reign of the risen Christ offers, but also with love for the oppressor and justice for all. Both Dalit theology in India and Black theology in the United States are more exclusively focused on the minority group whose faith they seek to express. Dalits, they claim, have their own participation in the liberating presence of the suffering Christ. They can only bear witness to God's promise for all people if they are not integrated into the ethos of the majority, of Hindu India, or even of the Christian church dominated by other castes. Similarly, for James H. Cone (1969, 1975), Christ's affirmation of black

people is central to God's liberating purpose, and salvation for white people means identifying with this experience. Minjung theologians speak in and for the church, but they understand the experience of the people of God and the suffering messiah in the Bible as offering God's promise and hope to the suffering people of Korea today. It is the minjung who are the messianic people.

These theologies differ in their identification of oppressed peoples seeking liberation, though they communicate with and learn from one another. Their views on the relation between these peoples and the church are not the same, though all have grown out of the church and speak to it. They are not always of one mind about the use of violence in the struggle against oppressive powers, though they all would condemn hatred and seek non-violent methods where possible. They do not all agree about the relation between the struggle of the poor for political, economic, and social liberation and the ultimate freedom promised in the coming of the kingdom of God. But for all of them Christian faith is fundamental. This means for them God's special concern for the poor in their fight for justice and freedom, God's identification with them in the servanthood and suffering of Christ, and God's promise of a world in which both oppressed and oppressors will be freed from power and domination. The movement has been called utopian, a term that Gutiérrez accepts as a provisional expression of Christian hope. Whether it is also realistic, history must judge.

## LIBER DE CAUSIS

The *Liber de Causis* (or *Liber Aristotelis de Expositione Bonitatis Purae*; Book of Causes) is a Latin translation of an Arabic work that is derived from the “Elements of Theology” of Proclus (fifth century CE). The author of the Arabic work is unknown; some scholars consider it the twelfth-century composition of David the Jew (Abraham ibn Daud or Avendath) at Toledo, while others believe it an eighth- or ninth-century product of a school of Neoplatonism in the Near East, possibly stemming from a still earlier Syriac source.

At least one Latin translation appeared before 1187, probably the product of the Toledan translator, Gerard of Cremona. The work then came to be ascribed variously to David, al-Fārābī, or Aristotle. By 1255 the Parisian Faculty of Arts, considering it a work of Aristotle, included it in the curriculum.

Among the many doctrines contained in the 211 chapters, or Propositions, of Proclus's “Elements of Theology,” the following should be noted. Proclus uses the term *theology* to mean Neoplatonic metaphysics. The latter describes the necessary procession of the world, or being, from its ultimate origins. The most important of these originative principles are: first, the gods; second, the pure spirits, or Intelligences; third, souls. The supreme god, or the One, is not describable as “being,” yet it is the universal cause of every being. Before producing Intelligences, the One effects a pair of opposite principles, Limit and Infinity, and then a series of subordinate gods, or “henads,” which have the causal function of Plato's Forms. The immediate effect of each principle, whether the latter be a god, a spirit, or a soul, is an attribute that is

both similar to, and yet more specific than, its source. The particularity of the effect is due to its recipient. Consequently, it is difficult for the reader to see how the One can produce all things without the cooperation of its subordinates.

The thirty-two propositions of the *Liber de Causis* summarize this material with the following changes: (1) the multitude of deities (Limit, Infinity, and henads) is eliminated and divinity is reserved to the One alone; (2) the first cause is described as “being” and its causality as “creation.” These changes suggest that the Neoplatonic author was either Jewish, Islamic, or Christian. Nevertheless, because the causes of Proclus act solely from the necessity of their natures and are mutually interdependent, it is questionable whether the *Liber de Causis* actually presents a monotheistic theory of free creation.

After reading William of Moerbeke’s Latin translation of the “Elements of Theology” (*Elementatio Theologica*, 1268), St. Thomas Aquinas noticed for the first time that the *Liber de Causis* was not a work of Aristotle, but a modification of Proclus. Unfortunately, this discovery had to be made again during the Renaissance.

The doctrines in the *Liber de Causis* influenced many thinkers, among them: William of Auvergne, Roger Bacon, Albert the Great, John Duns Scotus, and Meister Eckhart.

## LIBERTARIANISM

Libertarians like to think of themselves as defenders of liberty. For example, Friedrich A. von Hayek sees his work as restating an ideal of liberty for “We are concerned with that condition of men in which coercion of some by others is reduced as much as possible in society” (1960, p. 11). Similarly, John Hospers believes that libertarianism is “a philosophy of personal liberty—the liberty of each person to live according to his own choices, provided that he does not attempt to coerce others and thus prevent them from living according to their choices” (1971, p.5). And Robert Nozick (1974) claims that, if a conception of justice goes beyond libertarian “side-constraints,” it cannot avoid the prospect of continually interfering with people’s lives.

Libertarians have interpreted their ideal of liberty in two basically different ways. Some, following Herbert Spencer (1820–1903), have taken a right to liberty as basic and have derived all other rights from this right to liberty. Others, following John Locke, have taken a set of rights, including typically a right to life and a right to property, as basic and have defined liberty as the absence of constraints in the exercise of these rights. Both groups of libertarians regard liberty as the ultimate political ideal, but they do so for different reasons. For Spencerian libertarians liberty is the ultimate political ideal because all other rights are derived from a right to liberty. For Lockean libertarians liberty is the ultimate political ideal because liberty is just the absence of constraints in the exercise of people’s fundamental rights.

## SPENCERIAN AND LOCKEAN LIBERTARIANS

Consider the view of Spencerian libertarians, who take a right to liberty to be basic and define all other rights in terms of this right to liberty. According to this view liberty is usually interpreted as being unconstrained by other persons from doing what one wants or is able to do. Interpreting liberty this way, libertarians like to limit constraints to positive acts (i.e., acts of commission) that prevent people from doing what they otherwise want or are able to do. In contrast, welfare liberals and socialists interpret constraints to include, in addition, negative acts (acts of omission) that prevent people from doing what they otherwise want or are able to do. In fact, this is one way to understand the debate between defenders of *negative liberty* and defenders of *positive liberty*. This is because defenders of negative liberty interpret constraints to include only positive acts of others that prevent people

from doing what they otherwise want or are able to do, while defenders of positive liberty interpret constraints to include both positive and negative acts of others that prevent people from doing what they otherwise want or are able to do.

Suppose then we interpret constraints in the manner favored by libertarians to include only positive acts by others that prevent people from doing what they otherwise want or are able to do. Libertarians go on to characterize their political ideal as requiring that each person should have the greatest amount of liberty commensurate with the same liberty for all. From this ideal they claim that a number of more specific requirements, in particular a right to life, a right to freedom of speech, press, and assembly, and a right to property, can be derived.

Here, it is important to observe that the libertarian's right to life is not a right to receive from others the goods and resources necessary for preserving one's life. It is not a right to welfare: It is simply a right not to be killed unjustly. Correspondingly, the libertarian's right to property is not a right to receive from others the goods and resources necessary to meet one's basic needs, but a right to acquire goods and resources either by initial acquisitions or by voluntary agreements.

Of course, libertarians would allow that it would be nice of the rich to share their surplus goods and resources with the poor. Nevertheless, they deny that government has a duty to provide for such needs. Libertarians claim that some good things, such as providing welfare to the needy, are requirements of charity rather than justice. Accordingly, failure to make such provisions is neither blameworthy nor punishable. As a consequence, libertarians contend that such acts of charity should not be coercively required. For this reason they are opposed to any coercively supported welfare program.

For a similar reason libertarians are opposed to coercively supported opportunity programs. This is because the basic opportunities one has under a libertarian conception of justice are primarily a function of the property one controls, and since unequal property distributions are taken to be justified under a libertarian conception of justice, unequal basic opportunities are also regarded as justified.

The same opposition to coercively supported welfare and equal opportunity programs characterizes Lockean libertarians, who take a set of rights, typically including a right to life and a right to property, as basic and then interpret liberty as being unconstrained by other persons from doing what one has a right to do. According to this

view a right to life is simply a right not to be killed unjustly; it is not a right to receive welfare. Correspondingly, a right to property is a right to acquire property either by initial acquisitions or by voluntary transactions; it is not a right to receive from others whatever goods and resources one needs to maintain oneself. Understanding a right to life and a right to property in this way, libertarians reject both coercively supported welfare programs and equal opportunity programs as violations of liberty.

## A PARTIAL DEFENSE

In support of their view libertarians advance examples of the following sort. The first two are adapted from Milton Friedman (1962), and the last one is from Robert Nozick (1974).

In the first example you are to suppose that you and three friends are walking along the street and you happen to notice and retrieve a \$100 bill lying on the pavement. Suppose a rich fellow had passed by earlier throwing away \$100 bills, and you have been lucky enough to find one of them. Now, according to Friedman, it would be nice of you to share your good fortune with your friends. Nevertheless, they have no right to demand that you do so, and hence, they would not be justified in forcing you to share the \$100 bill with them. Similarly, Friedman would have us believe that it would be nice of us to provide welfare to the less fortunate members of our society. Nevertheless, the less fortunate members have no right to welfare, and hence they would not be justified in forcing us to provide such.

The second example, which Friedman regards as analogous to the first, involves supposing that there are four Robinson Crusoes, each marooned on four uninhabited islands in the same neighborhood. One of these Crusoes happens to land on a large and fruitful island, which enables him to live easily and well. The others happen to land on tiny and rather barren islands from which they can barely scratch a living. Suppose one day they discover the existence of each other. Now, according to Friedman, it would be nice of the fortunate Crusoe to share the resources of his island with the other three Crusoes, but the other three Crusoes have no right to demand that he share those resources, and it would be wrong for them to force him to do so. Correspondingly, Friedman thinks it would be nice of us to provide the less fortunate in our society with welfare, but the less fortunate have no right to demand that we do so, and it would be wrong for them to force us to do so.

In the third example Nozick asks us to imagine that we are in a society that has just distributed income

according to some ideal pattern, possibly a pattern of equality. We are further to imagine that in such a society someone with the talents of Wilt Chamberlain or Michael Jordan offers to play basketball for us provided that he receives one dollar from every home game ticket that is sold. Suppose we agree to these terms, and two million people attend the home games to see this new Wilt Chamberlain or Michael Jordan play, thereby securing for him an income of \$2 million. Since such an income would surely upset the initial pattern of income distribution whatever that happened to be, Nozick contends that this illustrates how an ideal of liberty upsets the patterns required by other conceptions of justice and calls for the rejection of these conceptions of justice.

### THE MINIMAL OR NIGHT-WATCHMAN STATE

Libertarians think that only a minimal or night-watchman state can be justified in terms of their ideal of liberty. The libertarian argument for the minimal or night-watchman state begins with the acceptable premise that voluntary agreements represent an ultimate ideal for social interaction. This ideal, libertarians contend, finds its fullest expression in a market economy where buyers and sellers, employers and employees, voluntarily agree to exchange the goods they possess. Thus, it is assumed that the requirements for voluntary agreements between persons with unequal resources are easily satisfied in a market economy. As long as alternative contractual arrangements make it possible for buyers and sellers, employers and employees, to take their business elsewhere, libertarians believe that agreements reached in market transactions are completely voluntary. On these grounds libertarians claim that the only significant role left for the state is to prevent and rectify departures from a market economy resulting from fraud, theft, or the use of force. Any more extensive role for the state, they contend, would restrict people's liberty; that is to say, it would restrict liberty understood negatively as the absence of interference by other persons. Accordingly, libertarians conclude that only a night-watchman state can be justified in terms of an ideal of negative liberty.

The libertarian argument for the night-watchman state also seeks to show that other social ideas cannot justify a more extensive state. Libertarians either maintain that other social ideals purporting to justify a more extensive state are themselves without justification, or they claim that these social ideals have lower priority when compared with the ideal of negative liberty. But there are not always agreements as to which critical approach is

appropriate. Thus with respect to an ideal of equality, Nozick (1974) and Hayek (1960) adopt different approaches: Nozick maintains that an ideal of equality has not been effectively justified, while Hayek maintains that the ideal has some validity but that negative liberty is the superior ideal. Allowing for such disagreements, both critical approaches could also be used by libertarians against various conceptions of positive liberty.

Nozick even goes so far as to claims that taxation of earnings from labor is on a par with forced labor. Still, libertarians are not similarly sensitive to the loss of liberty that occurs in the marketplace. For example, when an employer decides to lay someone off, Hospers (1971) claims that the employer is simply deciding against continuing a voluntary exchange and is not restricting the person's liberty. Likewise, Hayek (1960) claims that as long as workers who are laid off can find alternative employment their liberty is not being restricted. But how can requiring a person to pay \$500 into a social security program under threat of greater financial loss infringe on the person's liberty when requiring a person to take a job paying \$500 less under threat of greater financial loss does not infringe on the person's liberty? Surely it would seem that if one requirement restricts a person's liberty, the other will also.

To distinguish these cases, some libertarians claim that only intentional interference by others restricts a person's liberty. Requiring a person to pay \$500 into a social security program under threat of greater financial loss, they contend, is intentional interference by others and hence restricts the person's liberty, while requiring a person to take a job paying \$500 less under a similar threat is but the unintended result of individuals trying to better themselves in a market economy and hence does not restrict the person's liberty. But whether interference with a person's life is intentional or not is relevant only when determining the extent to which others are responsible for that interference. Although people are clearly more responsible for actions done intentionally they can still be responsible for actions done unintentionally, especially if they were morally negligent and should have foreseen the consequences of their actions. Since moral responsibility can extend to both intentional and unintentional interference with a person's life, there seems to be no reason for not considering both types of interference to be restrictions of a person's liberty. What is crucial to liberty as a social ideal is whether people are morally responsible for interfering with a person's life irrespective of whether that interference is intentional or not.

## A BASIC DIFFICULTY

A basic difficulty with the libertarian's conception of justice is the claim that rights to life and property, as the libertarian understands these rights, derive from an ideal of liberty. Why should we think that an ideal of liberty requires a right to life and a right to property that excludes a right to welfare? Surely it would seem that a right to property (as the libertarian understands it) might well justify a rich person's depriving a poor person of the liberty to acquire the goods and resources necessary for meeting his or her basic nutritional needs. How then could we appeal to an ideal of liberty to justify such a deprivation of liberty? Surely we couldn't claim that such a deprivation is justified for the sake of preserving a rich person's freedom to use the goods and resources he or she possesses to meet luxury needs. By any neutral assessment it would seem that the liberty of the deserving poor not to be interfered with when taking from the surplus possessions of the rich what they require to meet their basic needs would have priority over the liberty of the rich not to be interfered with when using their surplus possessions to meet their luxury needs. But if this is the case, then a right to welfare, and possibly a right to equal opportunity as well, would be grounded in the libertarian's own ideal of liberty.

## LIBERTY

One of the central concerns of social and political philosophy has been the issue of what limits, if any, there are to

the right of the state to restrict the “liberty” of its citizens. Unless one is convinced of the truth of anarchism, there are some actions with which the state may legitimately interfere, and unless one accords no value to personal liberty, there are some actions the state must leave to the discretion of the individual. One of the tasks of political philosophy is to develop and elaborate a theory to determine where these boundaries lie.

In his classical defense of liberalism—*On Liberty*—John Stuart Mill gave one influential answer to this question. The only reason that could justify the use of coercion against a person is to prevent harm to other people. Such a reason might not be decisive—it might be that the use of coercion would be ineffective or too costly or would violate the rights of privacy—but it brings the action in question within the scope of legitimate state power.

Other reasons, according to Mill, do not justify legal coercion. One cannot restrict someone's actions because they are harmful to that person; paternalism is not legitimate. One cannot restrict someone's actions because they are wrong or immoral (but not harmful to others); legal moralism is not legitimate. One cannot restrict someone's actions because his or her character would be improved by doing so; moral paternalism is not legitimate.

Obviously, a theory that puts such heavy weight on the notion of harm gives rise to disputes about the nature and limits of that notion. If conduct is offensive to others, does that count as harming them? If not, do we need a separate principle to justify prohibiting offensive conduct such as public nudity or racist graffiti? If we are competing for a job and you get it, am I harmed by this? Does only physical damage count as harm or emotional damage as well? Am I harmed by simply knowing that behind the walls of your house you are engaged in activities that I would find repulsive or wicked? If someone defaces the flag, is anyone harmed by this? If I consent to some action that is otherwise damaging to me, am I still harmed? Can I be harmed after my death—for example, by attacks on my reputation?

One of the most fully developed views that seeks to provide answers to these and similar questions is that of Joel Feinberg. He argues that any notion of harm that is going to play a role in answering normative questions will itself be normative in character. He accordingly defines the notion of harm in terms of a wrongful setback to a person's interests. To some extent, naturally, this shifts philosophical attention to the concept of interests.

## PATERNALISM

The normative issue raised by paternalism is when, if ever, the state or an individual is entitled to interfere with a person for that person's good. Examples of laws that have been justified in paternalistic terms include requiring motorcyclists to wear helmets, forcing patients to receive blood transfusions against their wishes, or requiring individuals to save for their retirement (Social Security).

The reasons that support paternalism are those that support any benevolent action—promoting the welfare of a person. The reasons against are those that militate against any interference with the autonomy of individuals—respect for their desire to lead their own lives. Normative debates about the legitimacy of paternalism involve disputes about many issues including the nature of welfare (can we produce good for a person against that individual's preferences and evaluations?), the correctness of various normative theories (consequentialism vs. autonomy or rights-based theories), and the relevance of hypothetical consent (in Mill's famous example of the man walking across a bridge that, unknown to him, is about to collapse, we may stop him, since he would not want to cross the bridge if he knew its condition).

## LEGAL MORALISM

The issue of whether the state may enforce morality—the subject that was brought to philosophical prominence by the debate between Lord Devlin and H. L. A. Hart—is present in discussions of the legalization of homosexuality, pornography, surrogate motherhood, and active euthanasia. The focus of such discussion is not the harm of such activities but their immorality and whether if they are immoral that is sufficient reason for the state to proscribe them. Since it is clearly the case that one of the grounds for proscribing murder is its immorality, the question arises as to what it might mean to deny that the state should take morality into account in limiting liberty. The best answer is that we may distinguish within the immoral different realms—for example, matters having to do with rights as opposed to matters having to do with ideals of conduct. Those who are opposed to the enforcement of morality are really opposed to enforcing certain areas of morality. Much of the discussion goes on under the heading of the “neutrality” of the liberal state.

## LICHTENBERG, GEORG CHRISTOPH

(1742–1799)

Georg Christoph Lichtenberg, the German satirist, scientist, and philosopher, studied mathematics and science at the University of Göttingen and was a professor there from 1767 to the end of his life. On two occasions Lichtenberg visited England. His impressions from these visits are recorded in his diaries and letters.

Lichtenberg's original contributions to mathematics and to pure and experimental science are not of great importance. The Lichtenberg figure in the theory of electricity was named after him. He was very successful as a teacher; among his pupils were Alexander von Humboldt and Christian Gauss. It has been said that his fame as a lecturer and demonstrator surpassed that of any other German scientist of his time.

His literary reputation with his contemporaries rested mainly on his satirical criticism of the writers of the *Sturm und Drang* movement and of the Swiss clergyman Johann Lavater's quasi-scientific psychology of character. Lichtenberg's own favorites and models in art were Englishmen: William Shakespeare; David Garrick, the actor; and William Hogarth, the painter. His analyses and descriptions of Garrick on the stage and his detailed “explanations” of Hogarth's etchings have become famous. Most of Lichtenberg's literary output during his lifetime appeared in two periodicals, of which he was the editor, the *Göttinger Taschen-Calender* and the *Göttingisches Magazin der Wissenschaften und Litteratur*.

By far the most valuable part of Lichtenberg's literary work, however, consisted of his "aphorisms," or scattered thoughts on psychological, philosophical, scientific, and many other topics. They were written down in notebooks but were never systematically arranged by the author. Nor were they used as raw material to any great extent for the more systematic work that Lichtenberg was constantly planning but never carried out. *Vermischte Schriften*, a comprehensive selection of his remarks, was published soon after his death.

Philosophically, Lichtenberg was not attached to any school or movement. The thinkers who made the deepest impressions on him were Benedict de Spinoza and Immanuel Kant. It is noteworthy that Lichtenberg was an early reviver of the great Jewish philosopher and one of the first to understand and acknowledge the revolutionary significance of Kant's transcendental philosophy. Furthermore, the versatility of his philosophical intellect is shown by his acute understanding of the work of Jakob Boehme.

Lichtenberg has had but a modest influence on the development of thought, but it is evident from the observations of Kant and Alexander von Humboldt, among others, that his contemporaries greatly prized his philosophical intellect. Subsequent generations were first made aware of his status as an independent thinker through the observation of Ernst Mach (in his *The Analysis of Sensations*) that Lichtenberg had anticipated the empiriocritical solution of the ego problem with his critique of the Cartesian *cogito ergo sum*. (In another work, "Die Leitgedanken meiner naturwissenschaftlichen Erkenntnislehre" [The primary ideas of my scientific epistemology], 1919, p. 5, Mach even hinted that he had been influenced by Lichtenberg.) Moreover, the affinity of Lichtenberg's ideas with modern linguistic philosophy has been indicated by various writers, for example, Friedrich Waismann in the preface to Moritz Schlick's *Gesammelte Aufsätze* and Richard von Mises in *Positivism*.

## PHILOSOPHY OF MATHEMATICS

Lichtenberg, in contradistinction to Kant, distinguished sharply between pure and applied mathematics and separated mathematics as a logico-deductive formalism from mathematics as a theory of reality.

The truths of pure mathematics are not only certain in a strict sense but are derived (in principle) independently of experience and empirical observation. A blind man, for instance, could discover the laws of light by means of the calculus, for as soon as the fundamental facts of refraction and reflection are discovered experi-

mentally, "the whole of dioptrics and catoptrics becomes a purely geometrical problem," which can be treated without further knowledge of natural processes. For this reason the ideal form of a scientific theory is that of a logico-deductive system. Lichtenberg stated: "The aim of the physicists is to prepare the way for mathematics."

In his conception of pure mathematics, Lichtenberg approached the notion of the analytical, or tautological, character of mathematical truths. He did not take a positive stand on Kant's view of the synthetic a priori character of mathematics, but it is evident from his remarks that he viewed it with suspicion.

Mathematics shapes its own world. The business of the physicist is to decide which "of the innumerable suppositions possible" is the single true one. The results of mathematical deduction cannot be asserted in advance to agree with the results of physical inquiry. "Their agreement is a purely empirical coincidence, nothing else." (It is apparent from his manuscript that Lichtenberg ascribed great importance to this remark.) Thus Lichtenberg renounced all a priori claims concerning the application of mathematics to reality.

Instead of being astounded at the actual success of mathematics in the exploration of natural phenomena, Lichtenberg emphasized the approximate character of mathematical laws of nature and warned of the temptation to read more mathematics into things than is actually there. "All mathematical laws that we find in nature, despite their beauty, are doubtful to me." The forms in which nature covers herself are too manifold and changeable to be comprehended exhaustively by our own conceptual apparatus. These thoughts, which had come early to Lichtenberg, were closely connected with his highly developed talent for observation and his acute feeling for the concrete.

It is characteristic that the work with which Lichtenberg qualified for his professorship was devoted to the study of an alleged discrepancy between theory and experience. This work, "Considerations about Some Methods for Removing a Certain Difficulty in the Calculation of Probability in Gambling" (not mentioned in J. M. Keynes's bibliography in his *Treatise on Probability*), concerned a famous problem of the theory of probability, the so-called Petersburg paradox, which engaged many leading mathematicians of the eighteenth century, among others, Jean Le Rond d'Alembert and Daniel Bernoulli. It is erroneous, however, to see in this problem, as Lichtenberg and others have done, a contradiction between the mathematical calculus and the actual course of events.

Recognition is due Lichtenberg for his scientific genius in being one of the first to see the possibility of denying, without contradiction, the Euclidean axioms. That between two points only one straight line can be drawn is indeed an accepted axiom, but it is by no means necessary. One can also conceive of the possibility that several distinct lines might pass through the same two points. The manner in which Lichtenberg attempted to show this possibility was, indeed, less significant: He imagined one could take arcs with the radii  $\infty$ ,  $\infty^2$ ,  $\infty^3$ , and so on, so that they proceed through two fixed points, describing distinct straight lines.

Interestingly enough, Lichtenberg also expressed some thoughts about the deflection of light through gravitation. As an adherent of Isaac Newton's corpuscular theory, he assumed that light has mass, from which it follows that a beam of light must deviate from a straight path because of its weight. "Light alone appears to be an exception (viz., to the curved path of most bodies); however, since it is probably heavy, it will be deflected as a result."

#### EPISTEMOLOGY OF THE EXACT SCIENCES

Lichtenberg realized the great significance of the discovery of structural identities among qualitatively different domains of theoretical research into nature. His idea of *paradigmata* (patterns), according to which processes were to be "declined," seems to have approached James Clerk Maxwell's view of the significance of analogy and to have anticipated the concept of isomorphism. Lichtenberg called discovery through *paradigmata* the most fruitful of all the heuristic devices of science. As an example of an application he suggested that one might use Newton's *Optics* as a model in the theory of the calcination of metals.

Lichtenberg had a clear view of the logic of constructing hypotheses: "If we want to understand nature," he said, "we must begin with sensible appearances." Hypotheses that transcend the evidence of the senses may only be constructed insofar as they can be tested within the domain of appearances. Concepts whose presence or absence in the individual case can never be demonstrated but only assumed are not permissible in science. The concept of ether in physics belongs to this category. The ether, which "no one has seen or felt, ... condensed, rarified, etc.," is like the notion of the world soul: Since it has no experiential consequences, it must be eliminated once and for all from a rational physics.

In spite of his opposition in principle to hypothesis making in physics, Lichtenberg did not agree with the

view that all assumptions should be discarded if, although they have testable consequences, they do not literally correspond to sensible reality. Assumptions of this kind may nonetheless be useful as pictures of complicated courses of events, and thus facilitate the application of mathematics to nature. (The notion of "picture," reminiscent of Heinrich Hertz's *Principles of Mechanics*, turns up often in Lichtenberg.) "If someone could make a clock that presented the movements of the heavenly bodies as exactly as actually obtains, would he not deserve much credit, even though the world does not operate by means of cog-wheels? Through this machine he could discover many things that he would not have believed to be present in it." In addition to such mechanical models, the two theories of light and atomic theory also belong to this category.

The truth content of scientific assumptions of the type mentioned above is proportional to their explanatory power and to their relative simplicity. Lichtenberg quite aptly noted that with theories as complex as that of light "it can no longer be merely a question of what is true, but of what manner of explanation is the simplest." And he added, "The door to truth is through simplicity." Moreover, his speculation that one could attempt to combine the corpuscular and wave theories sounds very modern.

The falsification of such hypotheses can not be established beyond question by empirical circumstances. A single negative instance does not in general make it necessary to renounce a comprehensive scientific theory that has otherwise been well confirmed. "One should take special note of contradictory experiences," wrote Lichtenberg, "until there are enough of them to make constructing a new system worthwhile."

#### SOUL AND MATTER, REALISM AND IDEALISM

Early in his career Lichtenberg rejected the idea of the soul as a substance. Before enough was understood to explain the phenomena of the world scientifically, spirits were accepted as explanations of phenomena. As our knowledge of the physical world increased, however, the boundaries of the spiritual realm shrank until finally "that which haunts our body and produces effects in it" was the only thing left that required a ghost for an explanation. The case of the "soul" is like that of phlogiston: In the end both substances dissipate into nothingness. What remains is a "bare word" comparable to the word *state* (*Zustand*), to which, however, one may at least attribute

heuristic value as a picture and as a type of idea innate in the human being.

According to Lichtenberg, the thesis of materialism is “the asymptote of psychology.” In psychology, he linked himself closely with the materialistic-mechanistic association theories of the Englishmen David Hartley and Joseph Priestley. A one-to-one correspondence obtains between the mental occurrence and the state of the brain, so that the former can, in principle, be inferred from the latter.

Lichtenberg, however, did not accept metaphysical materialism. Parallel with his critique of the concept of the soul went a critique of the concept of matter. Soul and inert matter are mere abstractions, he wrote in a letter in 1786; we know of matter and of soul only on the basis of the *forces* (*Kräfte*) through which they manifest themselves and “with which they are identical.” We postulate for these forces in one case “an inert receptacle and call it matter.” Through such a hypostatization, which is just a “chimera” of the brain, arises “the infamous dualism in the world”: the division of being into body and soul, spirit and matter. But in reality everything is one.

This acknowledgment of monism still bore a metaphysical character. It is probable that the influence of Spinoza had its effect on the position taken by Lichtenberg in 1786, since the letter of that year referred directly to Spinoza. But we may observe that, much earlier, Lichtenberg had expressed the same opinion almost word for word. However, it is not impossible that the influence of Spinoza was already at work then. Even in his earliest books of aphorisms there were remarks of a Spinozistic character, although the name of the great thinker was not mentioned.

Later, Lichtenberg’s monism took a more epistemological turn in that he clearly indicated how the basis of his monistic system should be interpreted. “We are aware only of the existence of our sensations, ideas, and thought,” he said and expressed the same thought with the words, “Everything is feeling (*Gefühle*).” We experience a part of our impressions as dependent upon us, another as independent of the perceiving subject: in this way we arrive at the difference between the inner and outer worlds.

To argue from sensations to an “ego” as their bearer, as René Descartes does, is not logically warranted. Lichtenberg remarked very perceptively: “One should say, ‘There is thinking,’ just as one says, ‘There is lightning.’” To say *cogito* is to say too much; for as soon as one translates it as “I think,” it seems necessary to postulate an ego.

Lichtenberg’s earlier critique of the idea of the soul culminates here in a critique of the self, somewhat reminiscent of the position of David Hume.

It took considerable effort on Lichtenberg’s part to attain clarity on the question of how we proceed from our sensations to things outside us. He perceived the significance of the problem from his study of Kant, and in his treatment of it we can generally discern Kant’s influence.

At first it was very difficult for Lichtenberg to rid himself of the idea that something in the actual world might correspond to our representations, although we can have “no conception at all of the true nature of the outside world.” But later he recognized that the question “whether things outside ourselves really exist and exist as we see them” is in fact “completely meaningless.” It is just as foolish as asking whether the color blue is really blue. We are compelled by our nature—this compulsion he termed, with Kant, *die Form der Sinnlichkeit* (form of sensibility)—to express ourselves in such way that we speak of certain objects of our perception as being outside ourselves and of others as being within us. “What is outside? What are objects *praeter nos*? What is the force of the preposition *praeter*? It is a purely human invention; a name to indicate a difference from other things which we call ‘not-*praeter nos*.’” “There is probably no one in the world who does not perceive this *difference*, and probably no such person will ever exist; and for philosophy that is enough. Philosophy need not go beyond this.”

Is not this standpoint “idealism”? Lichtenberg clearly perceived that, just as his critique of the idea of the “soul” did not result in metaphysical materialism, so his attitude toward the question of the reality of the outer world should not be confused with metaphysical idealism. Rather his doctrine stood beyond idealism and materialism in their traditional senses. “It is truly of little consequence to me whether one wants to label this idealism. Names have no significance. It is at least an idealism which, through idealism, acknowledges that there are things outside us.” What more can one ask? For human beings, “at least for the philosophical ones,” there is no other reality than the one so constituted. It is true that one is satisfied in ordinary life with some other, “lower station,” but whenever one begins to philosophize, one cannot but accept this enlightened point of view. “There is no other alternative,” he concluded.

## LICHTENBERG’S CONCEPTION OF PHILOSOPHY

“Our entire philosophy,” wrote Lichtenberg, “is a correction of linguistic usage.” What he meant by that is espe-

cially evident in his treatment of the question of realism. As indicated above, Lichtenberg's conception should not be understood as an attempt to deny the existence of things outside ourselves. That would have been a senseless undertaking. His intention was only to discover the meaning of the distinction between outer and inner objects by clearly presenting the facts that underlie this distinction. It turns out that the root of the traditional difficulty about the question of realism is that in ordinary life we attach a contradictory meaning to the expression "outside ourselves." When we have become conscious of this contradiction and have undertaken the proper correction of our linguistic usage, the difficulty vanishes of itself.

Philosophy, then, is a critique of language. Its goal, however, is not definitions of concepts. Lichtenberg was not of the opinion that one could, for philosophical use, replace the common language with an ideal language, perhaps in the sense of Gottfried Wilhelm Leibniz's *characteristica universalis*. Attempts to reform the nomenclature of the sciences did not find much favor with him. "To clarify words does not help," he said. Why? Because the interpretation of the clarified concepts takes place, in the final analysis, in the vernacular. But the vernacular, by its nature, is imbued with our false philosophy. The rectification of colloquial usage, which leads to true philosophy, is thus undertaken in the language of false philosophy: "We are therefore constantly teaching true philosophy with the language of the false one." The common philosophy, then, always maintains a certain superiority over the enlightened one, for the former is in possession of the "declensions and conjugations" of our language, and these are not changed by the clarification of meanings of words. "The invention of language preceded philosophy, and it is just this that makes philosophy difficult, particularly when one wishes to make it understandable to those who do not think much for themselves. Philosophy, whenever it speaks, is forced to speak the language of nonphilosophy... Pure philosophy still imperceptibly enjoys the pleasure of love with the impure (and cannot avoid doing so)."

The philosopher, then, speaks with the words of the common language about things that are beyond it. He is thus compelled to express himself, to a certain degree, in metaphors (*Gleichnissen*). He is supposed to direct our attention with his sentences to the false logic of our language, so that we learn to see the world correctly. He does not teach us a new language but helps us to express ourselves clearly with our own. "The peasant," said Lichtenberg, "uses all the sentences of the most abstract

philosophy, only they are entangled, hidden, confined, latent, as the physicist and chemist say; the philosopher gives us the pure sentences."

It should be evident from the above that Lichtenberg anticipated the conception of philosophy that has been represented in the twentieth century by Ludwig Wittgenstein. Wittgenstein knew Lichtenberg's work well and esteemed it highly. It is hardly possible, however, to speak of Lichtenberg as an influence on the philosophy of Wittgenstein. Nevertheless, a rare congeniality between the two men can be noted—not only in view of their conceptions of philosophy but also in view of their entire intellectual talents and temperaments.

(Berlin, 1902–1908); *Lichtenbergs Briefe*, edited by Albert Leitzmann and Carl Schüddelkopf, 3 vols. (Leipzig, 1901–1904).
- Lichtenberg's remarks on questions of mathematics and physics have been printed only in part. It is most unfortunate that all of his notes from the years 1779–1788 and the greater part of those from 1793–1796, which existed at the time of the first edition of the *Vermischte Schriften*, had been lost when Albert Leitzmann, in the beginning of the twentieth century, edited the *Aphorismen, nach den Handschriften*. This loss greatly complicates the task of reconstructing the course of development of Lichtenberg's thought. The selection of aphorisms in the *Vermischte Schriften* shows that some of his most important philosophical remarks were among those subsequently lost.
- For literature on Lichtenberg, see J. Dostal-Winkler, *Lichtenberg und Kant* (Munich, 1924); P. ## LIEBERT, ARTHUR

(1878–1946)

Arthur Liebert, the German neo-Kantian philosopher, was born Arthur Levi in Berlin. The son of a merchant, he spent six years in business after completing his secondary education in 1895. He then entered the University of Berlin, where he received his doctorate in 1908. After teaching at the Berlin Handelshochschule, Liebert lectured at the University of Berlin, becoming extraordinary professor in 1925. From 1918 to 1933 he was coeditor with Paul Menzer of *Kantstudien*, which became under their guidance an instrument of growing international cooperation in philosophy. Forced to leave Germany in 1933, when the National Socialists came to power, he was appointed professor of philosophy at the University of Belgrade and there founded the journal *Philosophia: Philosophorum Nostri Temporis Vox Universa*, which appeared at irregular intervals from 1936 to 1939. When the German armies invaded the Balkans, he found refuge in England, where he published *Das Wesen der Freiheit* (1944) and, together with other refugees, organized the Freier deutscher Kulturbund in Grossbritannien. At the end of World War II he returned to his restored professorship at Berlin, but he died shortly thereafter.

Liebert was influenced by the realistic interpretation given Immanuel Kant at Berlin by Friedrich Paulsen, Alois Riehl, and especially by Wilhelm Dilthey, who stressed the historical aspects of the *Geisteswissenschaften* (cultural sciences). Within this realistic neo-Kantian orientation, Liebert turned to the ethical problems of value and freedom and to the search for a dialectic movement of ethical and metaphysical categories in history. Many of his writings, particularly in his later years, were devoted to the promotion of worldwide philosophical cooperation as "the free guardian of freedom" and particularly to the development of a philosophical organization, "an Areopagus of mankind," within which the new humanism was to be promoted. This is the theme of "On the Duty of Philosophy in Our Age" (*Von der Pflicht der*

*Philosophie in unserer Zeit*), published during his exile in 1938.

Liebert's philosophical efforts to work out his critical metaphysics as a dialectic were to have taken the form of a large work titled *Geist und Welt der Dialektik*, of which only the first volume, *Grundlegung der Dialektik*, appeared (Berlin, 1929). To be distinguished from science, philosophy must accept as its field not simply being (*Sein*) but value (*Geltung*), for being not merely *is*, but *is valid* (*gilt*), or validates, itself. In opposition to the Baden neo-Kantians, Liebert rejected obligation (*Sollen*) as the ground of value, finding a new basis for metaphysics in the Kantian concern for the validation of judgments. "The right of metaphysics and the right to a metaphysics," he wrote, "flow from the idea and right of philosophy itself." The task of metaphysics thus becomes that of a historical "critical phenomenology" that "tests its own possibility and justification and derives its presuppositions and conclusions through reason."

Such a metaphysics does not merely use dialectic as the basis of metaphysical criticism but is itself dialectic. Its categories must include both philosophical ideas and the social and cultural contexts out of which they arise. "The idea of dialectic is at once the a priori condition and the definitive force (*massgebende Kraft*) for the construction of metaphysics, and also the distinctive instrument for penetrating into the nature of metaphysics, and for studying and understanding it." This dialectic must include within the scope of its critical and dynamic movement four motives: the intellectual, moral, aesthetic, and religious. Metaphysics is no longer "ontological-dogmatic" but "actualistic-critical"; the movement of its categorical structures of value combines temporal and supratemporal viewpoints. Its task is apparently never completed, because historical change outgrows the adequacy of every a priori structure. In particular, the modern world with its conflicts prevents a return to the classical humanizing harmonies of thought; the historical-normative dialectic that modern life calls forth must take the form of tragedy.

Liebert's lectures and seminars were devoted to the development and illustration of this conception of metaphysics. The *Grundlegung der Dialektik* provided only an introduction, in which Liebert traced the beginnings of the metaphysical dialectic in the thought of his contemporaries—practitioners of the *Geisteswissenschaften*; metaphysicians and theologians; and neo-Kantians and neo-Hegelians.

The Kantian identification of freedom with reason remained for Liebert the fixed a priori point of view of his

“actualistic-critical” metaphysics. He persistently attacked the currently popular forms of *Lebensphilosophie* as relativistic, irrational, and sacrificing philosophical freedom. Philosophers were called upon to fulfill their vocation by turning to metaphysics and ethics as guides for individual and organizational action against the forces of irrationalism and cultural decay.

Liebert’s thought has received little attention since his death. His most important writings are those in which he sought to formulate the principles of his own historical metaphysics of value.

## LIEBMANN, OTTO

(1840–1912)

Otto Liebmann, the German neo-Kantian philosopher, was born at Löwenberg (Lwówek Slaski), Silesia, and became successively *Privatdozent* at Tübingen (1865), extraordinary professor at Strassburg (1872), and professor at Jena (1882). He served as a volunteer during the siege of Paris in 1870 and 1871 and published a memoir of his experiences.

In a *Festschrift* dedicated to Liebmann on his seventieth birthday, various thinkers discussed the aspects of his work that were of particular interest to them. Each interpreted him differently; for example, Bruno Bauch stressed transcendental-methodological aspects, Erich Adickes empirical openness, Wilhelm Windelband critical-metaphysical insight. Such variegated criticism was not without foundation, for Liebmann’s thought had many facets and did not evolve so much as oscillate between impulsive outbursts and great restraint, passing from problem to problem.

In his notable early book, *Kant und die Epigonen* (1865), Liebmann swept aside the academic philosophy of his day and preached a return to Immanuel Kant. He simplified Kantian thought and streamlined the post-Kantian systems. The essence of the Kantian revolution, he claimed, was the discovery of the transcendental, which, however, must be freed from the *caput mortuum* of the thing-in-itself. The systematic effort of the great successors of Kant failed because Johann Gottlieb Fichte’s Ego, Friedrich Schiller’s Absolute, G. W. F. Hegel’s Spirit, Johann Friedrich Herbart’s “reals,” and Arthur Schopenhauer’s Will all represent the thing-in-itself, whereas J. F. Fries mistook the transcendental for the psychological. For Liebmann the only reality, immanent in consciousness and sufficient, is experience, which is both empirical reality and transcendental ideality. But could such simplified views be unequivocally developed?

In a subsequent essay, *Über den individuellen Beweis für die Freiheit des Willens* (1866), Liebmann dealt with the freedom of the will, in opposition to Schopenhauer. Are we, it can be asked, on the level of the transcendental or of the individual ego in dealing with this problem? Reexamining the question in 1901 (*Gedanken und Tatsachen*, Vol. II, p. 88), he referred it to the individual.

In *Über den objektiven Anblick* (1869) Liebmann distinguished three factors in perception: the sensitive, the intellectual, and the transcendent. The transcendent factor in perception “is the relationship between an unknown X and a likewise unknown Y, which appears to us as our body, and from which in turn there spring into our consciousness those sensitive qualities which our intellect transforms, according to a priori laws, into perceptible nature, a phenomenon of the external material world” (p. 153). In this work the thing-in-itself is not eliminated; on the contrary, two things-in-themselves—X and Y—are admitted.

Liebmann’s major works, *Analysis der Wirklichkeit* (1876) and *Gedanken und Tatsachen* (2 vols., 1882–1907), are collections of problems, not only in the critique of knowledge but also in *Naturphilosophie*, psychology, aesthetics, and ethics. In all of these, self-consciousness recognizes its limits; but the resulting agnosticism is superseded by a program of “critical metaphysics.”

In this connection Liebmann denounced as a *doktrinäre Fiktion* the neo-Baconian ideal (or idol) of pure experience, itself a notion that Liebmann took from Richard Avenarius and from the evolutionary genetic psychology of Herbert Spencer and others. Every experience and every science, Liebmann claimed, is possible only by means of certain nonempirical premises, such as

the principles of real identity, of the continuity of existence, of constant causality or legality, and of the temporal continuity of becoming, or, in general, by means of fundamental a priori forms or principles, which constitute the organization of human cognitive powers but from whose transcendental validity by no means necessarily follows its transcendent reality.

Liebmann distinguished three types of theories, which seek explanatory principles in the immediate empirical data, in hypotheses by which the phenomena are deduced, or in absolute metaphysical realities. He rejected the first and third, and admitted the hypotheses, if and as long as the facts confirm them. This is true not only of scientific but also of philosophical theories, especially of critical metaphysics as a “strict discussion of human views, human hypotheses on the essence of things.” Liebmann concentrated on the theories of science and their metaphysical pronouncements or assumptions. He claimed, for example, that the biological point of view is more than a mere postulation of an as-if; it is a positive affirmation of entelechies. Darwinism abounds with metascientific problems and teleological claims; but not even the transcendental philosopher can escape the problems posed by nature, with its own immanent logic (*Weltlogik*), its dynamic causality that achieves an increase in perfection, even though he knows that every hypothesis and system is a product of the specifically human thinking apparatus. A study of space and time that Liebmann undertook to come to grips with non-Euclidean viewpoints led him to problems that appeared to Windelband as idle fancies.

In dealing with the problem of the multiplicity of subjects, Liebmann developed but did not elaborate upon a distinction between three conceptions of the ego: the metaphysical substrate, an objective never attained by dogmatic metaphysics; the individual ego, a tacit assumption of psychology; and the transcendental ego, a “typical” subject of the intelligence of the human species and a fundamental condition of the empirical world. The problem of psychophysical parallelism led him to postulate a coincidence of natural and logical laws on the metaphysical plane of *natura naturans*, but he did not draw the necessary methodological distinctions to adequately treat this problem.

## LIFE, MEANING AND VALUE OF

To the questions “Is human life ever worthwhile?” and “Does (or can) human life have any meaning?” many religious thinkers have offered affirmative answers with the proviso that these answers would not be justified unless two of the basic propositions of most Western religions were true—that human life is part of a divinely ordained cosmic scheme and that after death at least some human beings will be rewarded with eternal bliss. Thus, commenting on Bertrand Russell’s statement that not only must each individual human life come to an end but that life in general will eventually die out, C. H. D. Clark contrasts this “doctrine of despair” with the beauty of the Christian scheme. “If we are asked to believe that all our striving is without final consequence,” then “life is meaningless and it scarcely matters how we live if all will end in the dust of death.” According to Christianity, on the other hand, “each action has vital significance.” Clark assures us that “God’s grand design is life eternal for those who walk in the steps of Christ. Here is the one grand incentive to good living.... As life is seen to have purpose and meaning, men find release from despair and the fear of death” (*Christianity and Bertrand Russell*, p. 30). In a similar vein, the Jewish existentialist Emil Fackenheim claims that “whatever meaning life acquires” is derived from the encounter between God and man. The meaning thus

conferred upon human life “cannot be understood in terms of some finite human purpose, supposedly more ultimate than the meeting itself. For what could be more ultimate than the Presence of God?” It is true that God is not always “near,” but “times of Divine farness” are by no means devoid of meaning. “Times of Divine nearness do not light up themselves alone. Their meaning extends over all of life.” There is a “dialectic between Divine nearness and Divine farness,” and it points to “an eschatological future in which it is overcome” (“Judaism and the Meaning of Life”).

Among unbelievers not a few maintain that life can be worthwhile and have meaning in some humanly important sense even if the religious world view is rejected. Others, however, agree with the religious theorists that our two questions must be given negative answers if there is no God and if death means personal annihilation. Having rejected the claims of religion, they therefore conclude that life is not worthwhile and that it is devoid of meaning. These writers, to whom we shall refer here as “pessimists,” do not present their judgments as being merely expressions of certain moods or feelings but as conclusions that are in some sense objectively warranted. They offer reasons for their conclusions and imply that anybody reaching a contradictory conclusion is mistaken or irrational. Most pessimists do not make any clear separation between the statements that life is not worthwhile and that life is without meaning. They usually speak of the “futility” or the “vanity” of life, and presumably they mean by this both that life is not worth living and that it has no meaning. For the time being we, too, shall treat these statements as if they were equivalent. However, later we shall see that in certain contexts it becomes important to distinguish between them.

Our main concern in this entry will be to appraise pessimism as just defined. We shall not discuss either the question whether life is part of a divinely ordained plan or the question whether we survive our bodily death. Our question will be whether the pessimistic conclusions are justified if belief in God and immortality are rejected.

### SCHOPENHAUER'S ARGUMENTS

Let us begin with a study of the arguments offered by the pessimists, remembering that many of these are indirectly endorsed by religious apologists. The most systematic and probably the most influential, though in fact not the gloomiest, of the pessimists was Arthur Schopenhauer. The world, he wrote, is something that ought not to exist: The truth is that “we have not to rejoice but rather to mourn at the existence of the world; that its non-

existence would be preferable to its existence; that it is something which ought not to be.” It is absurd to speak of life as a gift, as so many philosophers and thoughtless people have done. “It is evident that everyone would have declined such a gift if he could have seen it and tested it beforehand.” To those who assure us that life is only a lesson, we are entitled to reply: “For this very reason I wish I had been left in the peace of the all-sufficient nothing, where I would have no need of lessons or of anything else” (*The World as Will and Idea*, Vol. III, p. 390).

Schopenhauer offers numerous arguments for his conclusion. Some of these are purely metaphysical and are based on his particular system. Others, however, are of a more empirical character and are logically independent of his brand of metaphysical voluntarism. Happiness, according to Schopenhauer, is unobtainable for the vast majority of humankind. “Everything in life shows that earthly happiness is destined to be frustrated or recognized as illusion.” People either fail to achieve the ends they are striving for or else they do achieve them only to find them grossly disappointing. But as soon as a man discovers that a particular goal was not really worth pursuing, his eye is set on a new one and the same illusory quest begins all over again. Happiness, accordingly, always lies in the future or in the past, and “the present may be compared to a small dark cloud which the wind drives over the sunny plain: before and behind it all is bright, only it itself always casts a shadow. The present is therefore always insufficient; but the future is uncertain, and the past is irrevocable” (*ibid.*, p. 383). Men in general, except for those sufficiently rational to become totally resigned, are constantly deluded—“now by hope, now by what was hoped for.” They are taken in by “the enchantment of distance,” which shows them “paradises.” These paradises, however, vanish like “optical illusions when we have allowed ourselves to be mocked by them.” The “fearful envy” excited in most men by the thought that somebody else is genuinely happy shows how unhappy they really are, whatever they pretend to others or to themselves. It is only “because they feel themselves unhappy” that “men cannot endure the sight of one whom they imagine happy.”

On occasions Schopenhauer is ready to concede that some few human beings really do achieve “comparative” happiness, but this is not of any great consequence. For aside from being “rare exceptions,” these happy people are really like “decoy birds”—they represent a possibility that must exist in order to lure the rest of humankind into a false sense of hope. Moreover, happiness, insofar as it exists at all, is a purely “negative” reality. We do not

become aware of the greatest blessings of life—health, youth, and freedom—until we have lost them. What is called pleasure or satisfaction is merely the absence of craving or pain. But craving and pain are positive. As for the few happy days of our life—if there are any—we notice them only “after they have given place to unhappy ones.”

Schopenhauer not infrequently lapsed from his doctrine of the “negative” nature of happiness and pleasure into the more common view that their status is just as “positive” as that of unhappiness and pain. But he had additional arguments that do not in any way depend on the theory that happiness and pleasure are negative. Perhaps the most important of these is the argument from the “perishableness” of all good things and the ultimate extinction of all our hopes and achievements in death. All our pleasures and joys “disappear in our hands, and we afterwards ask astonished where they have gone.” Moreover, a joy that no longer exists does not “count”—it counts as little as if it had never been experienced at all:

That which *has been* exists no more; it exists as little as that which has *never* been. But of everything that exists you may say, in the next moment, that it has been. Hence something of great importance in our past is inferior to something of little importance in our present, in that the latter is a *reality*, and related to the former as something to nothing. (“The Vanity of Existence,” in *The Will to Live*, p. 229)

Some people have inferred from this that the enjoyment of the present should be “the supreme object of life.” This is fallacious; for “that which in the next moment exists no more, and vanishes utterly, like a dream, can never be worth a serious effort.”

The final “judgment of nature” is destruction by death. This is “the last proof” that life is a “false path,” that all man’s wishing is “a perversity,” and that “nothing at all is worth our striving, our efforts and struggles.” The conclusion is inescapable: “All good things are vanity, the world in all its ends bankrupt, and life a business which does not cover its expenses” (*The World as Will and Idea*, Vol. III, p. 383).

### THE POINTLESSNESS OF IT ALL

Some of Schopenhauer’s arguments can probably be dismissed as the fantasies of a lonely and embittered man who was filled with contempt for humankind and who was singularly incapable of either love or friendship. His own misery, it may be plausibly said, made Schopenhauer

overestimate the unhappiness of human beings. It is frequently, but not universally, true that what is hoped for is found disappointing when it is attained, and while “fearful envy” of other people’s successes is common enough, real sympathy and generosity are not quite so rare as Schopenhauer made them out to be. Furthermore, his doctrine that pleasure is negative while pain is positive, insofar as one can attach any clear meaning to it, seems glaringly false. To this it should be added, however, that some of Schopenhauer’s arguments are far from idiosyncratic and that substantially the same conclusions have been endorsed by men who were neither lonely nor embittered and who did not, as far as one can judge, lack the gift of love or friendship.

DARROW. Clarence Darrow, one of the most compassionate men who ever lived, also concluded that life was an “awful joke.” Like Schopenhauer, Darrow offered as one of his reasons the apparent aimlessness of all that happens. “This weary old world goes on, begetting, with birth and with living and with death,” he remarked in his moving plea for the boy-murderers Richard Loeb and Nathan Leopold, “and all of it is blind from the beginning to the end” (*Clarence Darrow—Attorney for the Damned*, edited by A. Weinberg, New York, 1957). Elsewhere he wrote: “Life is like a ship on the sea, tossed by every wave and by every wind; a ship headed for no port and no harbor, with no rudder, no compass, no pilot; simply floating for a time, then lost in the waves” (“Is Life Worth Living?,” p. 43). In addition to the aimlessness of life and the universe, there is the fact of death. “I love my friends,” wrote Darrow, “but they all must come to a tragic end.” Death is more terrible the more one is attached to things in the world. Life, he concludes, is “not worth while,” and he adds (somewhat inconsistently, in view of what he had said earlier) that “it is an unpleasant interruption of nothing, and the best thing you can say of it is that it does not last long” (“Is the Human Race Getting Anywhere?,” p. 53).

TOLSTOY. Lev Tolstoy, unlike Darrow, eventually came to believe in Christianity, or at least in his own idiosyncratic version of Christianity, but for a number of years the only position for which he could see any rational justification was an extreme form of pessimism. During that period (and there is reason to believe that in spite of his later protestations to the contrary, his feelings on this subject never basically changed) Tolstoy was utterly overwhelmed by the thought of his death and the death of those he cared for and, generally, by the transitory nature of all human achievements. “Today or tomorrow,” he

wrote in "A Confession," "sickness and death will come to those I love or to me; nothing will remain but stench and worms. Sooner or later my affairs, whatever they may be, will be forgotten, and I shall not exist. Then why go on making any effort?" Tolstoy likened the fate of man to that of the traveler in the Eastern tale who, pursued by an enraged beast, seeks refuge in a dry well. At the bottom of the well he sees a dragon that has opened its jaws to swallow him. To escape the enraged beast above and the dragon below, he holds onto a twig that is growing in a crack in the well. As he looks around he notices that two mice are gnawing at the stem of the twig. He realizes that very soon the twig will snap and he will fall to his doom, but at the same time he sees some drops of honey on the leaves of the branch and reaches out with his tongue to lick them. "So I too clung to the twig of life, knowing that the dragon of death was inevitably awaiting me, ready to tear me to pieces.... I tried to lick the honey which formerly consoled me, but the honey no longer gave me pleasure.... I only saw the unescapable dragon and the mice, and I could not tear my gaze from them. And this is not a fable but the real unanswerable truth."

These considerations, according to Tolstoy, inevitably lead to the conclusion that life is a "stupid fraud," that no "reasonable meaning" can be given to a single action or to a whole life. To the questions "What is it for?" "What then?" "Why should I live?" the answer is "Nothing can come of it," "Nothing is worth doing," "Life is not worthwhile."

What ways out are available to a human being who finds himself in this "terrible position"? Judging by the conduct of the people he observed, Tolstoy relates that he could see only four possible "solutions." The first is the way of ignorance. People who adopt this solution (chiefly women and very young and very dull people) have simply not or not yet faced the questions that were tormenting him. Once a person has fully realized what death means, this solution is not available to him. The second way is that of "Epicureanism," which consists in admitting the "hopelessness of life" but seizing as many of life's pleasures as possible while they are within reach. It consists in "disregarding the dragon and the mice and licking the honey in the best way, especially if much of it is around." This, Tolstoy adds, is the solution adopted by the majority of the people belonging to his "circle," by which he presumably means the well-to-do intellectuals of his day. Tolstoy rejects this solution because the vast majority of human beings are not well-to-do and hence have little or no honey at their disposal and also because it is a matter of accident whether one is among those who have

honey or those who have not. Moreover, Tolstoy observes, it requires a special "moral dullness," which he himself lacked, to enjoy the honey while knowing the truth about death and the deprivations of the great majority of men. The third solution is suicide. Tolstoy calls this the way of "strength and energy." It is chosen by a few "exceptionally strong and consistent people." After they realize that "it is better to be dead than to be alive, and that it is best of all not to exist," they promptly end the whole "stupid joke." The means for ending it are readily at hand for everybody, but most people are too cowardly or too irrational to avail themselves of them. Finally, there is the way of "weakness." This consists in seeing the dreadful truth and clinging to life nevertheless. People of this kind lack the strength to act rationally and Tolstoy adds that he belonged to this last category.

**STRENGTHS OF THE PESSIMIST POSITION.** Is it possible for somebody who shares the pessimists' rejection of religion to reach different conclusions without being plainly irrational? Whatever reply may be possible, any intelligent and realistic person would surely have to concede that there is much truth in the pessimists' claims. That few people achieve real and lasting happiness, that the joys of life (where there are any) pass away much too soon, that totally unpredictable events frequently upset the best intentions and wreck the noblest plans—this and much more along the same lines is surely undeniable. Although one should not dogmatize that there will be no significant improvements in the future, the fate of past revolutions, undertaken to rid man of some of his apparently avoidable suffering, does not inspire great hope. The thought of death, too, even in those who are not so overwhelmed by it as Tolstoy, can be quite unendurable. Moreover, to many who have reflected on the implications of physical theory it seems plain that because of the constant increase of entropy in the universe all life anywhere will eventually die out. Forebodings of this kind moved Bertrand Russell to write his famous essay "A Free Man's Worship," in which he concluded that "all the labors of the ages, all the devotion, all the inspiration, all the noonday brightness of human genius, are destined to extinction in the vast death of the solar system, and the whole temple of man's achievement must inevitably be buried beneath the debris of a universe in ruins." Similarly, Wilhelm Ostwald observed that "in the longest run the sum of all human endeavor has no recognizable significance." Although it is disputed whether physical theory really has such gloomy implications, it would perhaps be wisest to assume that the position endorsed by Russell and Ostwald is well-founded.

## COMPARATIVE VALUE JUDGMENTS ABOUT LIFE AND DEATH

Granting the strong points in the pessimists' claims, it is still possible to detect certain confusions and dubious inferences in their arguments. To begin with, there is a very obvious inconsistency in the way writers like Darrow and Tolstoy arrive at the conclusion that death is better than life. They begin by telling us that death is something terrible because it terminates the possibility of any of the experiences we value. From this they infer that nothing is really worth doing and that death is better than life. Ignoring for the moment the claim that in view of our inevitable death nothing is "worth doing," there very plainly seems to be an inconsistency in first judging death to be such a horrible evil and in asserting later on that death is better than life. Why was death originally judged to be an evil? Surely because it is the termination of life. And if something,  $y$ , is bad because it is the termination of something,  $x$ , this can be so only if  $x$  is good or has positive value. If  $x$  were not good, the termination of  $x$  would not be bad. One cannot consistently have it both ways.

To this it may be answered that life did have positive value prior to one's realization of death but that once a person has become aware of the inevitability of his destruction life becomes unbearable and that this is the real issue. This point of view is well expressed in the following exchange between Cassius and Brutus in William Shakespeare's *Julius Caesar* (III.i.102–105):

CASSIUS. Why he that cuts off twenty years of life—  
Cuts off so many years of fearing death.

BRUTUS. Grant that, and then is death a benefit:  
So are we Caesar's friends that have abridged  
His time of fearing death.

There is a very simple reply to this argument. Granting that some people after once realizing their doom cannot banish the thought of it from their minds, so much so that it interferes with all their other activities, this is neither inevitable nor at all common. It is, on the contrary, in the opinion of all except some existentialists, morbid and pathological. The realization that one will die does not in the case of most people prevent them from engaging in activities which they regard as valuable or from enjoying the things they used to enjoy. To be told that one is not living "authentically" if one does not brood about death day and night is simply to be insulted gratuitously. A person who knows that his talents are not as great as he would wish or that he is not as handsome as he would have liked to be is not usually judged to live "inauthenti-

cally," but on the contrary to be sensible if he does not constantly brood about his limitations and shortcomings and uses whatever talents he does possess to maximum advantage.

There is another and more basic objection to the claim that death is better than life. This objection applies equally to the claim that while death is better than life it would be better still not to have been born in the first place and to the judgment that life is better than death. It should be remembered that we are here concerned with such pronouncements when they are intended not merely as the expression of certain moods but as statements that are in some sense true or objectively warranted. It may be argued that a value comparison—any judgment to the effect that  $A$  is better or worse than  $B$  or as good as  $B$ —makes sense only if *both*  $A$  and  $B$  are, in the relevant respect, in principle open to inspection. If somebody says, for example, that Elizabeth Taylor is a better actress than Betty Grable, this seems quite intelligible. Or, again, if it is said that life for the Jews is better in the United States than it was in Germany under the Nazis, this also seems readily intelligible. In such cases the terms of the comparison are observable or at any rate describable. These conditions are fulfilled in some cases when value comparisons are made between life and death, but they are not fulfilled in the kind of case with which Tolstoy and the pessimists are concerned. If the conception of an afterlife is intelligible, then it would make sense for a believer or for somebody who has not made up his mind to say such things as "Death cannot be worse than this life" or "I wonder if it will be any better for me after I am dead." Achilles, in the *Iliad*, was not making a senseless comparison when he exclaimed that he would rather act

... as a serf of another,

A man of little possessions, with scanty means of subsistence,

Than rule as a ghostly monarch the ghosts of all the departed.

Again, the survivors can meaningfully say about a deceased individual "It is better (for the world) that he is dead" or the opposite. For the person himself, however, if there is no afterlife, death is not a possible object of observation or experience, and statements by him that his own life is better than, as good as, or worse than his own death, unless they are intended to be no more than expressions of certain wishes or moods, must be dismissed as senseless. At first sight the contention that in the circumstances under discussion value comparisons between life and death are senseless may seem implausible because of the widespread tendency to think of death as a shadowy kind

of life—as sleep, rest, or some kind of homecoming. Such “descriptions” may be admirable as poetry or consolation, but taken literally they are simply false.

### IRRELEVANCE OF THE DISTANT FUTURE

These considerations do not, however, carry us very far. They do not show either that life is worth living or that it “has meaning.” Before tackling these problems directly, something should perhaps be said about the curious and totally arbitrary preference of the future to the present, to which writers such as Tolstoy and Darrow are committed without realizing it. Darrow implies that life would not be “futile” if it were not an endless cycle of the same kind of activities and if instead it were like a journey toward a destination. Tolstoy clearly implies that life would be worthwhile, that some of our actions at least would have a “reasonable meaning,” if the present life were followed by eternal bliss. Presumably, what would make life no longer futile as far as Darrow is concerned is some feature of the destination, not merely the fact that it is a destination; and what would make life worthwhile in Tolstoy’s opinion is not merely the eternity of the next life but the “bliss” that it would confer—eternal misery and torture would hardly do. About the bliss in the next life, if there is such a next life, Tolstoy shows no inclination to ask “What for?” or “So what?” But if bliss in the next life is not in need of any further justification, why should any bliss that there might be in the present life need justification?

**THE LOGIC OF VALUE JUDGMENTS.** Many of the pessimists appear to be confused about the logic of value judgments. It makes sense for a person to ask about something “Is it really worthwhile?” or “Is it really worth the trouble?” if he does not regard it as intrinsically valuable or if he is weighing it against another good with which it may be in conflict. It does not make sense to ask such a question about something he regards as valuable in its own right and where there is no conflict with the attainment of any other good. (This observation, it should be noted, is quite independent of what view one takes of the logical status of intrinsic value judgments.) A person driving to the beach on a crowded Sunday, may, upon finally getting there, reflect on whether the trip was really worthwhile. Or, after undertaking a series of medical treatments, somebody may ask whether it was worth the time and the money involved. Such questions make sense because the discomforts of a car ride and the time and money spent on medical treatments are not usually judged to be valuable for their own sake. Again, a woman

who has given up a career as a physician in order to raise a family may ask herself whether it was worthwhile, and in this case the question would make sense not because she regards the raising of a family as no more than a means, but because she is weighing it against another good. However, if somebody is very happy, for any number of reasons—because he is in love, because he won the Nobel Prize, because his child recovered from a serious illness—and if this happiness does not prevent him from doing or experiencing anything else he regards as valuable, it would not occur to him to ask “Is it worthwhile?” Indeed, this question would be incomprehensible to him, just as Tolstoy himself would presumably not have known what to make of the question had it been raised about the bliss in the hereafter.

It is worth recalling here that we live not in the distant future but in the present and also, in a sense, in the relatively near future. To bring the subject down to earth, let us consider some everyday occurrences: A man with a toothache goes to a dentist, and the dentist helps him so that the toothache disappears. A man is falsely accused of a crime and is faced with the possibility of a severe sentence as well as with the loss of his reputation; with the help of a devoted attorney his innocence is established, and he is acquitted. It is true that a hundred years later all of the participants in these events will be dead and none of them will then be able to enjoy the fruits of any of the efforts involved. But this most emphatically does not imply that the dentist’s efforts were not worthwhile or that the attorney’s work was not worth doing. To bring in considerations of what will or will not happen in the remote future is, in such and many other though certainly not in all human situations, totally irrelevant. Not only is the finality of death irrelevant here; equally irrelevant are the facts, if they are facts, that life is an endless cycle of the same kind of activities and that the history of the universe is not a drama with a happy ending.

This is, incidentally, also the answer to religious apologists like C. H. D. Clark who maintain that all striving is pointless if it is “without final consequence” and that “it scarcely matters how we live if all will end in the dust of death.” Striving is not pointless if it achieves what it is intended to achieve even if it is without final consequence, and it matters a great deal how we live if we have certain standards and goals, although we cannot avoid “the dust of death.”

**THE VANISHED PAST.** In asserting the worthlessness of life Schopenhauer remarked that “what has been exists as little as what has never been” and that “something of great

importance now past is inferior to something of little importance now present.” Several comments are in order here. To begin with, if Schopenhauer is right, it must work both ways: If only the present counts, then past sorrows no less than past pleasures do not “count.” Furthermore, the question whether “something of great importance now past is inferior to something of little importance now present” is not, as Schopenhauer supposed, a straightforward question of fact but rather one of valuation, and different answers, none of which can be said to be mistaken, will be given by different people according to their circumstances and interests. Viktor Frankl, the founder of “logotherapy,” has compared the pessimist to a man who observes, with fear and sadness, how his wall calendar grows thinner and thinner as he removes a sheet from it every day. The kind of person whom Frankl admires, on the other hand, “files each successive leaf neatly away with its predecessors” and reflects “with pride and joy” on all the richness represented by the leaves removed from the calendar. Such a person will not in old age envy the young. “No, thank you,” he will think. “Instead of possibilities, I have realities in my past” (*Man’s Search for Meaning*, pp. 192–193).

This passage is quoted not because it contains any great wisdom but because it illustrates that we are concerned here not with judgments of fact but with value judgments and that Schopenhauer’s is not the only one that is possible. Nevertheless, his remarks are, perhaps, a healthy antidote to the cheap consolation and the attempts to cover up deep and inevitable misery that are the stock in trade of a great deal of popular psychology. Although Schopenhauer’s judgments about the inferior value of the past cannot be treated as objectively true propositions, they express only too well what a great many human beings are bound to feel on certain occasions. To a man dying of cancer it is small consolation to reflect that there was a time when he was happy and flourishing; and while there are undoubtedly some old people who do not envy the young, it may be suspected that more often the kind of talk advocated by the prophets of positive thinking is a mask for envy and a defense against exceedingly painful feelings of regret and helplessness in the face of aging and death and the now-unalterable past.

#### THE MEANINGS OF THE “MEANING OF LIFE”

Let us now turn to the question whether, given the rejection of belief in God and immortality, life can nevertheless have any “meaning” or “significance.” Kurt Baier has

called attention to two very different senses in which people use these expressions and to the confusions that result when they are not kept apart. Sometimes when a person asks whether life has any meaning, what he wants to know is whether there is a superhuman intelligence that fashioned human beings along with other objects in the world to serve some end—whether their role is perhaps analogous to the part of an instrument (or its player) in a symphony. People who ask whether history has a meaning often use the word in the same sense. When Macbeth exclaimed that life “is a tale/Told by an idiot, full of sound and fury,/Signifying nothing,” he was answering this cosmic question in the negative. His point evidently was not that human life is part of a scheme designed by a superhuman idiot but that it is not part of any design. Similarly, when Fred Hoyle, in his book *The Nature of the Universe* (rev. ed., New York, 1960), turns to what he calls “the deeper issues” and remarks that we find ourselves in a “dreadful situation” in which there is “scarcely a clue as to whether our existence has any real significance,” he is using the word *significance* in this cosmic sense.

On the other hand, when we ask whether a particular person’s life has or had any meaning, we are usually concerned not with cosmic issues but with the question whether certain purposes are to be found in his life. Thus, most of us would say without hesitation that a person’s life had meaning if we knew that he devoted himself to a cause (such as the spread of Christianity or communism or the reform of mental institutions), or we would at least be ready to say that it “acquired meaning” once he became sufficiently attached to his cause. Whether we approve of what they did or not, most of us would be ready to admit—to take some random examples—that Dorothea Dix, Louis Pasteur, V. I. Lenin, Margaret Sanger, Anthony Comstock, and Winston Churchill led meaningful lives. We seem to mean two things in characterizing such lives as meaningful: We assert, first, that the life in question had some dominant, overall goal or goals that gave direction to a great many of the individual’s actions and, second, that these actions and possibly others not immediately related to the overriding goal were performed with a special zest that was not present before the person became attached to his goal or that would not have been present if there had been no such goal in his life.

It is not necessary, however, that a person should be devoted to a cause, in the sense just indicated, before we call his life meaningful. It is sufficient that he should have some attachments that are not too shallow. This last expression is of course rather vague, but so is the use of

the word *meaning* when applied to human lives. Since the depth or shallowness of an attachment is a matter of degree, it makes perfectly good sense to speak of degrees of meaning in this context. Thus, C. G. Jung writes that in the lives of his patients there never was “sufficient meaning” (*Memories, Dreams, Reflections*, New York and Toronto, 1963, p. 140). There is nothing odd in such a locution, and there is equally nothing odd in saying about a man who has made a partial recovery from a deep depression that there is now again “some” meaning in his life.

Although frequently when people say about somebody that his life has or had meaning, they evidently regard this as a good thing, this is not invariably the case. One might express this point in the following way: Saying that attachment to a certain goal has made a man’s life meaningful is not tantamount to saying that the acts to which the goal has given direction are of positive value. A man might himself observe—and there would be nothing logically odd about it—“As long as I was a convinced Nazi (or communist or Christian or whatever) my life had meaning, my acts had a zest with which I have not been able to invest them since, and yet most of my actions were extremely harmful.” Even while fully devoted to his cause or goal the person need not, and frequently does not, regard it as intrinsically valuable. If challenged he will usually justify the attachment to his goal by reference to more fundamental value judgments. Thus, somebody devoted to communism or to medical research or to the dissemination of birth-control information will in all likelihood justify his devotion in terms of the production of happiness and the reduction of suffering, and somebody devoted to Christianity will probably justify his devotion by reference to the will of God.

Let us refer to the first of the two senses we have been discussing as the “cosmic” sense and to the second as the “terrestrial” sense. (These are by no means the only senses in which philosophers and others have used the word *meaning* when they have spoken of the meaning or meaninglessness of life, but for our purposes it is sufficient to take account of these two senses.) Now if the theory of cosmic design is rejected it immediately follows that human life has no meaning in the first or cosmic sense. It does not follow in the least, however, that a particular human life is meaningless in the second, or terrestrial, sense. This conclusion has been very clearly summarized by Baier: “Your life or mine may or may not have meaning (in one sense),” he writes, “even if life as such has none (in the other)... The Christian view guarantees a meaning (in one sense) to every life, the scientific view [what

we have simply been calling the unbeliever’s position] does not in any sense” (*The Meaning of Life*, p. 28). In the terrestrial sense it will be an open question whether an individual’s life has meaning or not, to be decided by the particular circumstances of his existence. It may indeed be the case that once a person comes to believe that life has no meaning in the cosmic sense his attachment to terrestrial goals will be undermined to such an extent that his life will cease to be meaningful in the other sense as well. However, it seems very plain that this is by no means what invariably happens, and even if it did invariably happen the meaninglessness of a given person’s life in the terrestrial sense would not logically follow from the fact, if it is a fact, that life is meaningless in the cosmic sense.

This is perhaps the place to add a few words of protest against the rhetorical exaggerations of certain theological writers. Fackenheim’s statement, quoted earlier, that “whatever meaning life acquires, it derives from the encounter between God and man” is typical of many theological pronouncements. Statements of this kind are objectionable on several grounds. Let us assume that there is a God and that meetings between God and certain human beings do take place; let us also grant that activities commanded by God in these meetings “acquire meaning” by being or becoming means to the end of pleasing or obeying God. Granting all this, it does not follow that obedience of God is the only possible unifying goal. It would be preposterous to maintain that the lives of all unbelievers have been lacking in such goals and almost as preposterous to maintain that the lives of believers never contain unifying goals other than obedience of God. There have been devout men who were also attached to the advance of science, to the practice of medicine, or to social reform and who regarded these ends as worth pursuing independently of any divine commandments. Furthermore, there is really no good reason to grant that the life of a particular person becomes meaningful in the terrestrial sense just because human life in general has meaning in the cosmic sense. If a superhuman being has a plan in which I am included, this fact will make (or help to make) my life meaningful in the terrestrial sense only if I know the plan and approve of it and of my place in it, so that working toward the realization of the plan gives direction to my actions.

#### IS HUMAN LIFE EVER WORTHWHILE?

Let us now turn to the question of whether life is ever worth living. This also appears to be denied by the pessimists when they speak of the vanity or the futility of human life. We shall see that in a sense it cannot be estab-

lished that the pessimists are “mistaken,” but it is also quite easy to show that in at least two senses that seem to be of importance to many people, human lives frequently are worth living. To this end, let us consider under what circumstances a person is likely to raise the question “Is my life (still) worthwhile?” and what is liable to provoke somebody into making a statement like “My life has ceased to be worth living.” We saw in an earlier section that when we say of certain acts, such as the efforts of a dentist or a lawyer, that they were worthwhile we are claiming that they achieved certain goals. Something similar seems to be involved when we say that a person’s life is (still) worthwhile or worth living. We seem to be making two assertions: First, that the person has some goals (other than merely to be dead or to have his pains eased) which do not seem to him to be trivial and, second, that there is some genuine possibility that he will attain these goals. These observations are confirmed by various systematic studies of people who contemplated suicide, of others who unsuccessfully attempted suicide, and of situations in which people did commit suicide. When the subjects of these studies declared that their lives were no longer worth living they generally meant either that there was nothing left in their lives about which they seriously cared or that there was no real likelihood of attaining any of the goals that mattered to them. It should be noted that in this sense an individual may well be mistaken in his assertion that his life is or is not worthwhile any longer: He may, for example, mistake a temporary indisposition for a more permanent loss of interest, or, more likely, he may falsely estimate his chances of achieving the ends he wishes to attain.

**DIFFERENT SENSES OF “WORTHWHILE.”** According to the account given so far, one is saying much the same thing in declaring a life to be worthwhile and in asserting that it has meaning in the “terrestrial” sense of the word. There is, however, an interesting difference. When we say that a person’s life has meaning (in the terrestrial sense) we are not committed to the claim that the goal or goals to which he is devoted have any positive value. (This is a slight oversimplification, assuming greater uniformity in the use of “meaning of life” than actually exists, but it will not seriously affect any of the controversial issues discussed here.) The question “As long as his life was dedicated to the spread of communism it had meaning *to him*, but was it really meaningful?” seems to be senseless. We are inclined to say, “If his life had meaning to him, then it had meaning—that’s all there is to it.” We are not inclined (or we are much less inclined) to say something of this kind when we speak of the worth of a person’s life. We

might say—for example, of someone like Adolf Eichmann—“While he was carrying out the extermination program, his life *seemed* worthwhile to him, but since his goal was so horrible, his life *was not* worthwhile.” One might perhaps distinguish between a “subjective” and an “objective” sense of “worthwhile.” In the subjective sense, saying that a person’s life is worthwhile simply means that he is attached to some goals that he does not consider trivial and that these goals are attainable for him. In declaring that somebody’s life is worthwhile in the objective sense, one is saying that he is attached to certain goals which are both attainable and of positive value.

It may be held that unless one accepts some kind of rationalist or intuitionist view of fundamental value judgments one would have to conclude that in the objective sense of “worthwhile” no human life (and indeed no human action) could ever be shown to be worthwhile. There is no need to enter here into a discussion of any controversial questions about the logical status of fundamental value judgments. But it may be pointed out that somebody who favors a subjectivist or emotivist account can quite consistently allow for the distinction between ends that only seem to have positive value and those that really do. To mention just one way in which this could be done: One may distinguish between ends that would be approved by rational and sympathetic human beings and those that do not carry such an endorsement. One may then argue that when we condemn such a life as Eichmann’s as not being worthwhile we mean not that the ends to which he devoted himself possess some nonnatural characteristic of badness but that no rational or sympathetic person would approve of them.

**THE PESSIMISTS’ SPECIAL STANDARDS.** The unexciting conclusion of this discussion is that some human lives are at certain times not worthwhile in either of the two senses we have distinguished, that some are worthwhile in the subjective but not in the objective sense, some in the objective but not in the subjective sense, and some are worthwhile in both senses. The unexcitingness of this conclusion is not a reason for rejecting it, but some readers may question whether it meets the challenge of the pessimists. The pessimist, it may be countered, surely does not deny the plain fact that human beings are on occasions attached to goals which do not seem to them trivial, and it is also not essential to his position to deny (and most pessimists do not in fact deny) that these goals are sometimes attainable. The pessimist may even allow that in a superficial (“immediate”) sense the goals which people try to achieve are of positive value, but he would add that because our lives are not followed by eternal bliss

they are not “really” or “ultimately” worthwhile. If this is so, then the situation may be characterized by saying that the ordinary man and the pessimist do not mean the same by “worthwhile,” or that they do mean the same in that both use it as a positive value expression but that their standards are different: The standards of the pessimist are very much more demanding than those of most ordinary people.

Anybody who agrees that death is final will have to concede that the pessimist is not mistaken in his contention that judged by his standards, life is never worthwhile. However, the pessimist is mistaken if he concludes, as frequently happens, that life is not worthwhile by ordinary standards because it is not worthwhile by his standards. Furthermore, setting aside the objection mentioned earlier (that there is something arbitrary about maintaining that eternal bliss makes life worthwhile but not allowing this role to bliss in the present life), one may justifiably ask why one should abandon ordinary standards in favor of those of the pessimist. Ordinarily, when somebody changes standards (for example, when a school raises or lowers its standards of admission) such a change can be supported by reasons.

But how can the pessimist justify his special standards? It should be pointed out here that our ordinary standards do something for us which the pessimist’s standards do not: They guide our choices, and as long as we live we can hardly help making choices. It is true that in one type of situation the pessimist’s standards also afford guidance—namely, in deciding whether to go on living. It is notorious, however, that whether or not they are, by their own standards, rational in this, most pessimists do not commit suicide. They are then faced with much the same choices as other people. In these situations their own demanding standards are of no use, and in fact they avail themselves of the ordinary standards. Schopenhauer, for example, believed that if he had hidden his antireligious views he would have had no difficulty in obtaining an academic appointment and other worldly honors. He may have been mistaken in this belief, but in any event his actions indicate that he regarded intellectual honesty as worthwhile in a sense in which worldly honors were not. Again, when Darrow had the choice between continuing as counsel for the Chicago and North Western Railway and taking on the defense of Eugene V. Debs and his harassed and persecuted American Railway Union, he did not hesitate to choose the latter, apparently regarding it as worthwhile to go to the assistance of the suppressed and not worthwhile to aid the suppressor. In other words, although no human action is worthwhile, some human

actions and presumably some human lives are less unworthwhile than others.

### IS THE UNIVERSE BETTER WITH HUMAN LIFE THAN WITHOUT IT?

We have not—at least not explicitly—discussed the claims of Schopenhauer, Eduard von Hartmann, and other pessimists that the nonexistence of the world would be better than its existence, by which they mean that a world without human life would be better than one with it.

**ARGUMENTS OF A PHENOMENOLOGIST.** Some writers do not think that life can be shown to have meaning in any philosophically significant sense unless an affirmative answer to this question can be justified. Thus, in his booklet *Der Sinn unseres Daseins* the German phenomenologist Hans Reiner distinguishes between the everyday question about what he calls the “need-conditioned” meaning of life, which arises only for a person who is already in existence and has certain needs and desires, and the question about the meaning of human life in general. The latter question arises in concrete form when a responsible person is faced with the *Zeugungsproblem*—the question whether he should bring a child into the world. Reiner allows that a person’s life has meaning in the former or “merely subjective” sense as long as his ordinary goals (chiefly his desire for happiness) are attained. This, however, does not mean that his life has an “objective” or “existential” (*seinshaft*) meaning—a significance or meaning that “attaches to life as such” and which, unlike the need-conditioned meaning, cannot be destroyed by any accident of fate. The philosopher, according to Reiner, is primarily concerned with the question of whether life has meaning in this objective or existential sense. “Our search for the meaning of our life,” Reiner writes, “is identical with the search for a logically compelling reason (*einen einsichtigen Grund*) why it is better for us to exist than not to exist” (*Der Sinn unseres Daseins*, p. 27). Again, the real question is “whether it is better that mankind should exist than that there should be a world without any human life” (p. 31). It may be questioned whether this is what anybody normally means when he asks whether life has any meaning, but Reiner certainly addresses himself to one of the questions raised by Schopenhauer and other pessimists that ought to be discussed here.

Reiner believes that he can provide a “logically compelling reason” why a world with human life is better than one without it. He begins by pointing out that men differ

from animals by being, among other things, “moral individuals.” To be a moral individual is to be part of the human community and to be actively concerned in the life of other human beings. It is indeed undeniable that people frequently fail to bring about the ends of morally inspired acts or wishes, but phenomenological analysis discloses that “the real moral value and meaning” of an act does not depend on the attainment of the “external goal.” As Immanuel Kant correctly pointed out, the decisive factor is “the good will,” the moral intent or attitude. It is here that we find the existential meaning of life: “Since that which is morally good contains its meaning and value within itself, it follows that it is intrinsically worth while. The existence of what is morally good is therefore better than its non-existence.” (*Der Sinn unseres Daseins*, pp. 54–55). But the existence of what is morally good is essentially connected with the existence of free moral individuals, and hence it follows that the existence of human beings as moral agents is better than their nonexistence.

Unlike happiness, which constitutes the meaning of life in the everyday or need-conditioned sense, the morally good does not depend on the accidents of life. It is not within a person’s power to be happy, but it is “essentially” (*grundsätzlich*) in everybody’s power to do what is good. Furthermore, while all happiness is subjective and transitory, leaving behind it no more than a “melancholy echo,” the good has eternal value. Nobody would dream of honoring and respecting a person for his happiness or prosperity. On the other hand, we honor every good deed and the expression of every moral attitude, even if it took place in a distant land and among a foreign people. If we discover a good act or a good attitude in an enemy we nevertheless respect it and cannot help deriving a certain satisfaction from its existence. The same is true of good deeds carried out in ages long past. In all this the essentially timeless nature of morality becomes evident. Good deeds cease to exist as historical events only; their value, on the other hand, has eternal reality and is collected as an indestructible “fund.” This may be a metaphysical statement, but it is not a piece of “metaphysical speculation.” It simply makes explicit what the experience of the morally good discloses to phenomenological analysis (*Der Sinn unseres Daseins*, pp. 55–57).

REPLIES TO REINER. There is a great deal in this presentation with which one could take issue. If one is not misled by the image of the ever-growing, indestructible “fund,” one may wonder, for example, what could be meant by claiming that the value of a good deed is “eternal,” other than that most human beings tend to approve

of such an action regardless of when or where it took place. However, we are here concerned primarily with the question whether Reiner has met the challenge of the pessimists, and it seems clear that he has not. A pessimist like Schopenhauer or Darrow might provisionally grant the correctness of Reiner’s phenomenological analysis of morality but still offer the following rejoinder: The inevitable misery of all or nearly all human beings is so great that even if in the course of their lives they have a chance to preserve their inner moral natures or their good will, the continued torture to which their lives condemn them would not be justified. Given the pessimist’s estimate of human life, this is surely not an unreasonable rejoinder. Even without relying on the pessimist’s description of human life, somebody while accepting Reiner’s phenomenological analysis might reach the opposite conclusion. He might, for example, share the quietist strain of Schopenhauer’s teachings and object to the whole hustle and bustle of life, concluding that the “peace of the all-sufficient nothing”—or, more literally, a universe without human life—was better in spite of the fact that moral deeds could not then be performed. Since he admits the “facts” of morality on which Reiner bases his case but considers the peace of the all-sufficient nothing more valuable than morality, it is not easy to see how an appeal to the latter would show him to be mistaken. What phenomenological analysis has not disclosed, to Reiner or, as far as is known, to anybody else, is that doing good is the only or necessarily the greatest value.

WHY THE PESSIMIST CANNOT BE ANSWERED. The conclusion suggests itself that the pessimist cannot here be refuted, not because what he says is true or even because we do not know who is right and who is wrong but because the question whether a universe with human life is better than one without it does not have any clear meaning unless it is interpreted as a request for a statement of personal preference. The situation seems to be somewhat similar to what we found in the case of the question “Is my life better than my death?” when asked in certain circumstances. In some contexts indeed when we talk about human life in general, the word *better* has a reasonably clear meaning. Thus, if it is maintained that life for the human race will be better than it is now after cancer and mental illness have been conquered, or that human life will be better (or worse) after religion has disappeared, we understand fairly well what is meant, what facts would decide the issue either way. However, we do not really know what would count as evidence for or against the statement “The existence of human life as such is better than its nonexistence.” Sometimes it is

claimed that the question has a fairly clear meaning, namely, whether happiness outweighs unhappiness. Thus, von Hartmann supports his answer that the nonexistence of human life is better than its existence, that in fact an inanimate world would be better than one with life, with the argument that as we descend the scale of civilization and “sensitivity,” we reach ever lower levels of misery. “The individuals of the lower and poorer classes and of ruder nations,” he writes, “are happier than those of the elevated and wealthier classes and of civilized nations, not indeed because they are poorer and have to endure more want and privations, but because they are coarser and duller” (*Philosophy of the Unconscious*, Vol. III, p. 76). The “brutes,” similarly, are “happier (i.e., less miserable)” than man, because “the excess of pain which an animal has to bear is less than that which a man has to bear.” The same principle holds within the world of animals and plants:

How much more painful is the life of the more finely-feeling horse compared with that of the obtuse pig, or with that of the proverbially happy fish in the water, its nervous system being of a grade so far inferior! As the life of a fish is more enviable than that of a horse, so is the life of an oyster than that of a fish, and the life of a plant than that of an oyster. (Ibid.)

The conclusion is inevitable: The best or least undesirable form of existence is reached when, finally, we “descend beneath the threshold of consciousness”; for only there do we “see individual pain entirely disappear” (*Philosophy of the Unconscious*, Vol. III, pp. 76–77). Schopenhauer, also, addressing himself directly to the “*Zeugungsproblem*,” reaches a negative answer on the ground that unhappiness usually or necessarily outweighs happiness. “Could the human race continue to exist,” he asks (in *Parerga und Paralipomena*, Vol. II, pp. 321–322), if “the generative act were ... an affair of pure rational reflection? Would not rather everyone have so much compassion for the coming generation as to prefer to spare it the burden of existence, or at least be unwilling to take on himself the responsibility of imposing such a burden in cold blood?” In these passages Schopenhauer and von Hartmann assume that in the question “Is a world with human life better than one without human life?” the word *better* must be construed in a hedonistic or utilitarian sense—and the same is true of several other philosophers who do not adopt their pessimistic answer. However, while one may stipulate such a sense for “better” in this context, it is clear that this is not what is meant prior to the stipulation. Benedict de Spinoza, for example, taught that the

most miserable form of existence is preferable to nonexistence. Perhaps few who have directly observed the worst agonies and tortures that may be the lot of human beings or of animals would subscribe to this judgment, but Spinoza can hardly be accused of a self-contradictory error. Again, Friedrich Nietzsche’s philosophy is usually and quite accurately described as an affirmation of life, but Nietzsche was very careful not to play down the horrors of much of life. While he did not endorse Schopenhauer’s value judgments, he thought that, by and large, Schopenhauer had not been far wrong in his description of the miseries of the human scene. In effect Nietzsche maintained that even though unhappiness is more prevalent than happiness, the existence of life is nevertheless better than its nonexistence, and this surely is not a self-contradiction.

It is important to point out what does not follow from the admission that in a nonarbitrary sense of “better,” the existence of the human race cannot be shown to be better than its nonexistence: It does not follow that I or anybody else cannot or should not prefer the continued existence of the human race to its nonexistence or my own life to my death, and it does not follow that I or anybody else cannot or should not enjoy himself or that I or anybody else is “irrational” in any of these preferences. It is also impossible to prove that in some nonarbitrary sense of “better,” coffee with cream is better than black coffee, but it does not follow that I cannot or should not prefer or enjoy it or that I am irrational in doing so. There is perhaps something a trifle absurd and obsessive in the need for a “proof” that the existence of life is better than its nonexistence. It resembles the demand to have it “established by argument” that love is better than hate.

Perhaps it would be helpful to summarize the main conclusions reached in this essay:

- (1) In certain familiar senses of “meaning,” which are not usually regarded as trivial, an action or a human life can have meaning quite independently of whether there is a God or whether we shall live forever.
- (2) Writers such as Tolstoy, who, because of the horror that death inspires, conclude that death is better than life, are plainly inconsistent. Moreover, the whole question of whether my life is better than my death, unless it is a question about my preference, seems to be devoid of sense.
- (3) Those who argue that no human action can be worthwhile because we all must eventually die

ignore what may be called the “short-term context” of much of our lives.

- (4) Some human lives are worthwhile in one or both of the two senses in which “worthwhile” is commonly used, when people raise the question of whether a given person’s life is worthwhile. The pessimists who judge human life by more demanding standards are not mistaken when they deny that by their standards no human life is ever worthwhile. However, they are guilty of a fallacious inference if they conclude that for this reason no human life can be worthwhile by the usual standards. Nor is it clear why anybody should embrace their standards in the place of those commonly adopted.
- (5) It appears that the pessimists cannot be answered if in order to answer them one has to be able to prove that in some nonarbitrary sense of the word *better*, the existence of life is better than its nonexistence. But this admission does not have any of the gloomy consequences that it is sometimes believed to entail.

### Bibliography

The position that human life cannot be meaningful without religious belief is defended in James Martineau, *Modern Materialism and Its Relation to Religion and Theology* (New York, 1877), and more recently in C. H. D. Clark, *Christianity and Bertrand Russell* (London: Lutterworth Press, 1958), and in E. L. Fackenheim, “Judaism and the Meaning of Life,” in *Commentary* 39 (1965): 49–55. Substantially similar views are expounded in Paul Althaus, “The Meaning and Purpose of History in the Christian View,” in *Universitas* 7 (1965): 197–204, and in various publications by Viktor Frankl. Frankl’s *Man’s Search for Meaning* (Boston: Beacon Press, 1963) contains a full list of his own writings as well as those of his followers, most of whom may be described as practicing “pastoral psychology.” A proreligious position is also advocated by William James in “Is Life Worth Living?,” in *The Will to Believe and Other Essays in Popular Philosophy* (New York: Longmans, Green, 1897), and *The Varieties of Religious Experience* (New York: Longmans, Green, 1902), Chs. 6 and 7. A milder version of the same position is presented in Chad Walsh, *Life Is Worth Living* (Cincinnati, no date).

Schopenhauer’s views about the “vanity” of life are stated in Vol. I, Bk. IV, of *Die Welt als Wille und Vorstellung* (Leipzig,

1818), translated by R. B. Haldane and J. Kemp as *The World as Will and Idea*, 3 vols. (London: Trubner, 1883), and in several of his pieces included in *Parerga und Paralipomena*, 6th ed., edited by J. Frauenstädt, 2 vols. (Berlin, 1851). Three of his essays that bear most closely on the subject of the present entry—“On the Vanity and Suffering of Life,” “On the Sufferings of the World,” and “The Vanity of Existence”—are available in an English translation by T. Bailey Saunders in *The Will to Live—Selected Writings of Arthur Schopenhauer*, edited by Richard Taylor (Garden City, NY: Doubleday, 1962).

Eduard von Hartmann’s position is stated in Vol. III of *Die Philosophie des Unbewussten*, 3 vols. (Berlin, 1869), translated by W. C. Coupland as *Philosophy of the Unconscious* (London, 1884), in *Zur Geschichte und Begründung des Pessimismus* (Berlin, 1892), and in *Philosophische Fragen der Gegenwart* (Leipzig: Haacke, 1885), Ch. 5. Clarence Darrow’s pessimism is expounded in *The Story of My Life* (New York: Scribners, 1932) and in two pamphlets, “Is Life Worth Living?” and “Is the Human Race Getting Anywhere?” (Girard, KS, no date). Tolstoy’s views are stated in “A Confession,” in *A Confession, the Gospel in Brief and What I Believe*, translated by Aylmer Maude (London: Oxford University Press, H. Milford, 1940). Gloomy implications are derived from the second law of thermodynamics by Bertrand Russell in “A Free Man’s Worship” (1903), which is available in several books, perhaps most conveniently in Russell’s *Mysticism and Logic* (London: Allen and Unwin, 1918), and by Wilhelm Ostwald, *Die Philosophie der Werte* (Leipzig: Kröner, 1913). F. P. Ramsey, in “How I Feel,” in *The Foundations of Mathematics and Other Logical Essays* (London: K. Paul, Trench, Trubner, 1931), agrees with Russell and Ostwald about the physical consequences of the second law but does not share their gloomy response. Stephen Toulmin, “Contemporary Scientific Mythology,” in Toulmin et al., *Metaphysical Beliefs* (London: SCM Press, 1957), questions whether the second law has the physical consequences attributed to it by Russell, Ostwald, and many others. L. J. Russell, “The Meaning of Life,” *Philosophy* 28 (1953): 30–40, contains some interesting criticisms of the view that eternal existence could render any human actions meaningful.

The fullest discussions of the questions of the meaning and value of life by contemporary analytic philosophers are Kurt Baier, *The Meaning of Life* (Canberra, 1957), parts of which are reprinted in *Twentieth Century Philosophy—The Analytic Tradition*, edited by Morris Weitz (New York: Free Press, 1966); Ronald W. Hepburn, *Christianity and Paradox* (London: Watts, 1958), Ch. 8; and Antony Flew, “Tolstoi and the Meaning of Life,” in *Ethics* 73 (1963): 110–118. Baier, Hepburn, and Flew support the position that life can be meaningful even if there is no God and no afterlife. This position is also defended in Eugen Dühring, *Der Werth des Leben* (Leipzig, 1881), Chs. 6–7, and more recently in Bertrand Russell, *The Conquest of Happiness* (New York: Liveright, 1930), Ch. 2; Ernest Nagel, “The Mission of Philosophy,” in *An Outline of Man’s Knowledge of the Modern World*, edited by Lyman Bryson (New York: McGraw-Hill, 1960); Sidney Hook, “Pragmatism and the Tragic Sense of Life,” in *Proceedings and Addresses of the American Philosophical Association* 33 (1960): 5–26; Karl R. Popper, *The Open Society and Its Enemies*, 2 vols. (5th rev. ed.,

London: Routledge and K. Paul, 1966), Vol. II, Ch. 25; and Kai Nielsen, "Examination of an Alleged Theological Basis of Morality," in *Ilf Review* 21 (1964): 39–49. Jean-Paul Sartre and Albert Camus are frequently (and rather inaccurately) described as "nihilists," but in effect they also take the position that although the universe is "absurd," human life can be meaningful. Sartre's views are found in *Being and Nothingness*, translated by Hazel E. Barnes (New York: Philosophical Library, 1956), Pt. 4. Camus's views are stated in *The Myth of Sisyphus and Other Essays*, translated by Justin O'Brien (New York: Knopf, 1955). Views very similar to those of Sartre and Camus are advocated by Flew and R. W. Hepburn in their BBC discussion "Problems of Perspective," which is printed in *Plain View* 10 (1955): 151–166. C. D. McGee, *The Recovery of Meaning—An Essay on the Good Life* (New York: Random House, 1966), Ch. 1, contains a lively and detailed discussion of some of the issues treated in the present entry. The author reaches similar conclusions but devotes far more attention to the "malaise" that inspires questions about the meaning of life. In a similar vein, Ilham Dilman, "Life and Meaning," in *Philosophy* 40 (1965): 320–333, concentrates on the psychological situations that prompt people to ask whether their own lives or the lives of others have meaning. Moritz Schlick, *Vom Sinn des Lebens* (Berlin, 1927), is concerned primarily with psychological questions, arguing that modern life tends to be spoiled by overemphasis on the achievement of distant goals. Sigmund Freud in several places alludes to the question of the meaning of life and usually dismisses it as senseless and pathological. "The moment a man questions the meaning and value of life," he wrote in a letter to Marie Bonaparte, "he is sick.... By asking this question one is merely admitting to a store of unsatisfied libido to which something else must have happened, a kind of fermentation leading to sadness and depression" (*Letters of Sigmund Freud*, translated by James Stern and Tania Stern, edited by E. L. Freud, New York: Dover, 1960, p. 436).

The Polish Marxist Adam Schaff deals with some of the issues discussed in the present entry in his *A Philosophy of Man* (London: Lawrence and Wishart, 1963). Schaff's views are criticized from a Christian point of view in Christopher Hollis, "What Is the Purpose of Life?," in *Listener* 70 (1961): 133–136. There is a discussion of the "meaning of life" from the point of view of fascism in Mario Palmieri, *The Philosophy of Fascism* (Chicago: Dante Alighieri Society, 1936). The "phenomenological" position of Hans Reiner, which was discussed in the final section of this entry, is stated in his *Der Sinn unseres Daseins* (Tübingen, 1960). Other more recent German works include *Sinn und Sein*, edited by Richard Wisser (Tübingen: Niemeyer, 1960); Reinhart Lauth, *Die Frage nach den Sinn des Daseins* (Munich, 1953); and Johannes Hessen, *Der Sinn des Lebens* (Cologne, 1933).

Psychological studies of people who attempted or who committed suicide are contained in Margarethe von Andics, *Suicide and the Meaning of Life* (London: Hodge, 1947); Louis I. Dublin and Bessie Bunzel, *To Be or Not to Be* (New York: H. Smith and R. Haas, 1933); and E. Stengel, *Suicide and Attempted Suicide* (London: MacGibbon and Kee, 1965).

Will Durant, *On the Meaning of Life* (New York: R. Long & R.R. Smith, 1932), consists of answers by various eminent men, including Mohandas Gandhi, H. L. Mencken, Russell, and George Bernard Shaw, to the question of what they take to be the meaning of life.

*Paul Edwards (1967)*

## LIFE, MEANING AND VALUE OF [ADDENDUM]

Paul Edwards primarily addresses the "pessimist view" that if there is no God and death is final, life has no meaning. The focus here will be on subsequent philosophical work and on issues he leaves unaddressed. Some account of nonmonotheistic religion (Buddhism, Daoism, Confucianism, and Advaita Vedanta Hinduism) should be given, especially since religious perspectives are now taken more seriously by many in the analytic philosophical tradition.

Thomas Nagel (1986) argues both that (1) human life viewed objectively is insignificant though viewed subjectively is significant and that (2) it is our capacity to recognize both (1) and our constitutional self-absorption, which makes us irreducibly absurd and our lives ironic. Against (1) David Wiggins (2002) argues that for our strivings to matter, even subjectively, there must be something we can "invest with overwhelming *importance*," and that this entails both that values are objective, though "lit up by the focus one brings to the world", and that happiness is not supremely important. Robert Nozick (1989) shares this view and imagines a hermetically sealed "experience machine" that can undetectably provide apparently real and happy experiences involving others. Would a life be better lived inside the machine in a state of perpetual happiness or outside, with the tribulation and joys of genuine connection to others? Nozick argues for the latter, distinguishing between intrinsic value and meaning. The measure of a thing's intrinsic value is the degree of its diversity and the degree of the organic unity of that diversity. Meaning comes from a thing's connection to other things with intrinsic value—the greater their value and the stronger the connection, the greater the meaning. Thus, value is proportional to both internal integration and the strength of external connections to things of great value.

Turning to religious accounts, Philip Quinn (2000) distinguishes axiological and teleological questions. He argues that an integrated life might have intrinsic or "axiological value" though it lacked any overt connection to a

transcendent reality that would give it “teleological value.” Keith Ward argues, “What distinguishes a religious view of nontrivial purpose is that all positive human purposes are subordinate to the one objective purpose of attaining the supreme goal of union with, or fulfilling relation to, the supreme value...” (Ward 2000, p. 20). Still, a life may be intrinsically valuable, worthwhile (to oneself) and reasonably happy, without being specially valuable or meaningful, and it may be meaningful and, thus, valuable without being somehow ultimately valuable.

Now if there is a transcendent entity such as God, Brahman, Nirvana, or the Dao, then one’s connectedness to it, assuming a connection of great diversity to other centers of value such as people, would bring an ultimate or teleological meaning to life, obviating the absurdity that Nagel posits. Asian philosophical traditions view normal human nature as inadequate though improvable through self-reflection and right moral action; the Indic traditions, however, offer a bleaker view of human nature than the Chinese. For both, a life of value and meaning is only possible if one aligns the self with the underlying relational structure of reality: the Dao (Chinese traditions) or the Dharma (Hinduism and Buddhism). Daoism holds that meaning is achieved by returning to the natural self in accordance with the Dao, whereas Confucianism, which developed religious notions of a transcendent reality after Mahayana Buddhism entered China, emphasizes refinement, also holding that, as Tu Wei-Ming puts it, “we can realize the ultimate meaning of life in ordinary human existence” (Tu 1985, p. 60).

For Indic traditions, an illusory view of the self leads to an attachment to this life, preventing the attainment of meaning through a transcendent being (Brahman) or a state (Nirvana), “the fullness of being” and the “fullness of emptiness,” respectively. Within Hinduism, Sankara’s Advaita Vedanta holds Atman (the true self) identical to Brahman. The majority Hindu position of *bhakti yoga*, espoused by Ramajuna and closer to monotheism, focuses on the key teaching that Eliot Deutsch identifies in the *Bhagavad Gita*: that nonattachment is only possible via a new attachment to that of greatest value. “One overcomes the narrow clinging to results ... only when that passion is replaced by one directed to the Divine” (Deutsch 1968, p. 163). Still, even if there is a transcendent reality, the best is not an enemy of the good, so axiological and teleological meaning can be compatible and even inextricably linked. “A man who knows his own nature will know Heaven” says Mencius, and Masao Abe articulates the meaning of life in Mahayana Zen this way:

“For the sake of wisdom, do not abide in *samsara* (this life); for the sake of compassion, do not abide in *nirvana*” (Abe 2000, p. 161).

## LIFE, ORIGIN OF

Two explanations dominated prescientific thinking about the origin of life: special creation and spontaneous generation. According to the former view, supernatural intervention was essential for the creation of life; according to the latter, living organisms could form spontaneously—for example, from the mud of the Nile. Not surprisingly, special creation was usually favored as an explanation of the origin of humans and the higher animals, whereas spontaneous generation seemed adequate to explain the origin of insects, frogs, and even mice.

The theory of spontaneous generation came under attack in the seventeenth century when the Italian scientist Francesco Redi showed that maggots do not arise spontaneously in rotting meat but develop from eggs laid

by flies. The spontaneous generation controversy persisted for another two hundred years or so until the classic experiments of Louis Pasteur convinced almost everyone that even microorganisms appear only as the descendants of similar microorganisms. This posed the problem of the origin of life in its modern form: How were the first organisms generated from abiotic matter?

The generally accepted answer to this question was provided by the theory of evolution through natural selection as proposed by Charles Darwin and Alfred Russell Wallace. Darwin in the final paragraph of the first edition of "On the Origin of Species" suggests that the whole complex world of life has evolved from one or a few simple kinds of organism that were formed on the Earth long ago. "There is a grandeur in this view of life with its several powers, having been originally breathed into a few forms or into one, and that, whilst this planet has gone cycling on according to the fixed law of gravity, from so simple a beginning endless forms most beautiful and most wonderful have been, and are being, evolved" (1859, chapter 14).

Darwin never published his thoughts on the origin of those earliest organisms, probably to avoid upsetting his wife, but in a much-quoted letter he speculates that life may have emerged "in some warm little pond with all sorts of ammonia and phosphoric salts, light, heat, electricity, etc., present" (1959 [1898], pp. 202–203). Thus Darwin thought that, long ago, a complex mixture of organic molecules was formed spontaneously on the Earth "in some little pond," and that they supported the appearance of the first simple living organisms. After that, the evolution of the whole biosphere was the consequence of natural selection acting on those earliest organisms and their descendants. Modern research on the origin of life is largely concerned with filling in the details of Darwin's scenario.

### THE NATURE OF THE PROBLEM

The Earth is about 4.6 billion years old. The dating of the earliest fossil microorganisms remains somewhat controversial, but it seems almost certain that organisms not unlike modern bacteria or algae were already present on the Earth about 3.5 billion years ago. During the first half-billion years of Earth's history repeated impacts of comets, asteroids, and other interplanetary objects would have sterilized the Earth's surface, so up to half a billion years was available for the evolution of complex life from abiotic origins. There is no reason to doubt that this was long enough.

DNA sequencing and the comparison of the genomes of different organisms have revolutionized human understanding of the evolutionary relationships between the varied forms of life. While many details remain to be worked out, people already have a reasonable picture of the nature of the last common ancestor of all life, and a fairly detailed outline of the sequence in which the different fossil and extant forms of life evolved from it. The many gaps in the picture are likely to be filled in during the early twenty-first century. The outstanding problem, therefore, is that of the origin of the first living, replicating microorganisms. Most scientists believe that they originated on the Earth, although the possibility that they were brought here from elsewhere in the solar system cannot be dismissed out of hand.

### EARLY EXPERIMENTAL STUDIES

The modern era of experimental origin-of-life studies began in 1953 with the classical experiments of Harold Urey and Stanley Miller. Alexandre Ivanovich Oparin in 1924 had suggested that the organic material needed to get life started was formed in the atmosphere of the Earth when the atmosphere was still reducing. Miller, then a graduate student working with Urey, tested this hypothesis by passing an electric discharge through a "reducing atmosphere" of methane, water, and ammonia. To the surprise of his contemporaries, Miller was able to detect among the products substantial amounts of several of the amino acids that are present in proteins. This was the first successful experiment designed to demonstrate that important components of contemporary living organisms are readily formed from simple starting materials under prebiotic conditions.

In the years following Miller's experiment, most of the organic molecules that are central to molecular biology were obtained by related methods. The discovery by Juan Oro that adenine, a component both of nucleic acids and of ATP, the energy currency of the cell, could be formed from a simple solution of ammonium cyanide was particularly impressive. However, this whole approach came under attack when it was realized that the atmosphere of the Earth could never have been as strongly reducing as Miller and Urey assumed. Whether it was ever sufficiently reducing to support similar chemistry, even if less efficiently, is uncertain.

A second possible source of the organic material needed to permit the origin of life was identified in the carbonaceous chondrites, a common class of meteorite. Careful chemical analysis showed that these stones contained abundant organic material, including amino acids

and the nucleic acid bases. Many scientists believe that meteorites, comets, and interplanetary dust provided much of the organic material for the origin of life.

In the late twentieth century another possible source of prebiotic organic material was identified, namely the deep-sea vents. In the vents, superheated water containing large amounts of metal sulfides comes into contact with cold seawater causing the sulfides to precipitate. Laboratory experiments suggest that metal sulfides can act as catalysts for the formation of a mixture of a variety of organic molecules from volcanic gases. Clearly, there are several possible sources of the prebiotic organic material needed for the origin of life, but it is not clear which of them was most important.

### THE RNA WORLD

The most important recent advance in our understanding of the origin of life is the realization that there once was an RNA world. The modern biological world depends on a complex, interacting system of proteins and nucleic acids in which proteins are needed to replicate nucleic acids, but the formation of proteins depends on the prior presence of nucleic acids. It is now known that the DNA/RNA/protein world was preceded by a much simpler world in which RNA, without the help of proteins, fulfilled both a genetic and a functional role.

It is now clear from laboratory experiments that RNA molecules are capable of evolution by natural selection and are capable of catalyzing a variety of difficult chemical reactions. In particular it has been possible to evolve an RNA catalyst that carries out the most important step involved in RNA replication. It seems probable, therefore, that RNA catalysts (ribozymes) once supported a fairly complex form of life, without the help of proteins. Thus the problem of the origin of life is simplified: How were the first replicating molecules of RNA synthesized on the primitive Earth?

Attempts to demonstrate the synthesis of RNA under prebiotic conditions have met with some success, but formidable difficulties remain. The monomeric components of RNA, ribonucleotides, are complicated organic molecules made up from a sugar, a heterocyclic purine or pyrimidine base, and an inorganic phosphate group. The prebiotic syntheses of the two organic components that have been reported are relatively inefficient and nonspecific, and the combination of the three elementary components to form ribonucleotides is complicated by several troublesome side reactions. A great deal of novel chemistry needs to be discovered before a plausible pre-

biotic synthesis of the nucleotides can be claimed. A number of scientists are working on the problem.

The formation of long polymers from ribonucleotides is another difficult step in the synthesis of RNA. However, substantial successes have been achieved in model systems. The most extensive studies make use of an abundant clay mineral, montmorillonite, to catalyze the polymerization of an analog of the activated nucleotides that are used in the enzymatic synthesis of RNA. This work emphasizes the important role that minerals are likely to have played in the origin of life. It seems probable that many of the most difficult reactions needed to get life started occurred on mineral surfaces rather than in solution.

The replication of DNA or RNA is dependent on specific base-pairing between adenylic acid and uridylic or thymidylic acid and between guanylic acid and cytidylic acid. Base pairing is an intrinsic property of the nucleotide bases, so that a preformed strand of RNA (DNA) will align the complementary mononucleotides in the correct sequence even in the absence of a protein enzyme. If the nucleotides are presented in an activated form suitable for incorporation into polymers, a preformed RNA (DNA) strand, therefore, will bring about the nonenzymatic synthesis of a new complementary strand. This process is known as template-directed synthesis.

Template-directed synthesis is a central theme in many scenarios for the origin of the RNA world. It has been shown, for example, that a great variety of RNA sequences can be "copied," that is a great variety of sequences will catalyze the synthesis of their complements, converting single-stranded RNA to double-stranded RNA. Thus mineral catalysis of the formation of long single-stranded RNA molecules followed by template-directed copying could, in principle, have assembled a complex mixture (library) of double-stranded RNA on the primitive Earth, but only if a supply of ribonucleotides was available.

It is possible to propose a scenario for the origin of the RNA world by optimistic extrapolation of the available experimental evidence. First nucleotides were formed abiotically; they condensed together on mineral surfaces to give single-stranded RNA that was then copied by template-directed synthesis to give a "library" of double-stranded RNA molecules. Among these was one that included an RNA polymerase that was able to get efficient RNA replication started.

The serious obstacles to the prebiotic synthesis of RNA have led many researchers to propose a different kind of solution to the problem of the origin of the RNA world. They believe that one or more much simpler biochemical worlds preceded the RNA world and “invented” RNA. The search for such simple worlds is just beginning, but there are already a number of RNA-like polymers that, although they are somewhat simpler than RNA, look as though they could have functioned as genetic systems. The search for even simple systems is an active field.

### SUMMARY

It is generally accepted that once a replicating genetic polymer appeared on the early Earth, evolution through natural selection could account for the appearance of ever more complex organisms, and finally of the familiar biosphere. It is known that one such evolving world, the RNA world, preceded the world of DNA, RNA, and proteins. Scientists do not know how the RNA world came into existence. There are several theories, but none is as yet supported by strong experimental evidence. Ongoing research should provide an answer sometime in the early twenty-first century.

## LIPPS, THEODOR

(1851–1914)

Theodor Lipps, a psychologist and philosopher, was born in Wallhalben, Rhineland-Palatinate. He studied theology and natural science at Erlangen, Tübingen, Utrecht, and Bonn. He obtained academic positions in Bonn (1884), Breslau (1890), and finally in Munich (1894), where he remained until his death. There he was a full professor and the teacher of Johannes Daubert and Alexander Pfänder, the founding members of the Munich circle of phenomenology. Lipps published voluminously on a large variety of topics, though his orientation in philosophy was consistently a psychological one.

In *Basic Facts of Mental Life* (1883) Lipps states his conception of philosophy as follows: “Inner experience is the basis for psychology, logic, aesthetics, ethics, and the adjunct disciplines, including metaphysics in the sense in which it is permissible to speak of it. We regard all these disciplines now as philosophical, and at least in the main they fill what is usually viewed as the range of tasks that we especially honor with the name of philosophical ones. Their objects are presentations, sensations, and volitional acts, and no intelligent person denies that such objects are different from the subject matters of other sciences and therefore require their own manner of scientific treatment” (p. 3). Thus he conceived of philosophy as equivalent to or based on psychology, with an emphasis on “inner perception.”

This psychological style of philosophy is also evident in Lipps’s views on logic. These in particular became subject to attack in Husserl’s critique of psychologism. By no means, however, was the close tie between philosophy and psychology unusual for the late nineteenth and early twentieth centuries. The empirically minded psychological turn that occurred in the German-speaking world at that time was an attempt to establish philosophy as a sci-

ence amid the skepticism that was rife in the aftermath of the collapse of the speculative systems of German Idealism. Although Lipps's philosophical endeavors arose in this context, his approach to psychology differs significantly from the approaches of most of his contemporaries. He was, for example, willing to allow not only for inner perception but also for introspection or self-observation (*Selbstbeobachtung*), a notion that was unacceptable to many other philosopher-psychologists of the time, most notably Franz Brentano and his orthodox followers, for whom inner perception can never become self-observation.

The subject matter of psychology, according to Lipps, consists of conscious experiences (*Bewusstseinslebnisse*), which always belong to an ego (*Ich*). It is, moreover, to be an empirical science. The ego to which conscious experiences belong—which is not to be confused with the soul (*Seele*)—is empirically given just as these experiences themselves are. “And the ego,” Lipps significantly adds, “can intentionally direct its gaze upon itself. It can itself be an ‘object.’ It can grasp and cognize itself” (1909, p. 6). Although this acceptance of the notion of self-observation put him at odds with Brentano and other contemporaries, Lipps had much in common with Brentano, Dilthey, and others insofar as he distinguished between two aspects of psychology as an empirical science: one descriptive and analytical, the other explanatory. The latter can involve physiological considerations and laboratory experiments in order to provide causal explanations of how conscious experiences arise, whereas the former makes no use of physiology or experimentation. It was this descriptive or “pure” psychology that primarily interested Lipps.

Lipps's most outstanding and enduring contribution is his concept of empathy (*Einfühlung*). This idea is of special importance because it was adopted and critically revised in such phenomenological theories of intersubjectivity as those developed by Husserl and Edith Stein. By means of empathy we come to know not only other minds but also other important objects of experience, such as those belonging to organic nature and works of art. One empathizes when one puts oneself in the place of—and even to some extent imitates—someone or something else. Lipps asserted with particular emphasis, contrary to some of his critics, that our knowledge of other minds is first and foremost grounded in empathy and thus in feelings rather than in purely intellectual operations. The pervasive role that he gave to empathy in his wide-ranging philosophical investigations naturally led to panpsychism in metaphysics.

The philosophy that Lipps developed out of his psychological studies was by no means subjectivistic or relativistic. This was certainly not the case with his logic. Moreover, in both aesthetics and ethics he thought it was possible to formulate universally valid prescriptions on the basis of psychology. As the science of the beautiful—of that which evokes or is suited to evoke the feeling of beauty (*Schönheitsgefühl*)—aesthetics aims to establish the psychological conditions under which such a feeling arises. Ethics, according to Lipps, is concerned with universally valid morality (*Sittlichkeit*) as opposed to the morals (*Moral*) of this or that historical period, nation, class, or individual. A Kantian influence is evident in his ethical reflections, in which the moral person (*sittliche Persönlichkeit*) is given the status of the highest good. In spite of this influence from Kant, however, Lipps presented a philosophical viewpoint that should be considered on its own merits and not merely in the shadow of his predecessors.

## LIPSIUS, JUSTUS (1547–1606)

Justus Lipsius, the Flemish humanist, classical philologist, and literary critic, foremost interpreter of Stoicism in the later Renaissance, and the founder of modern neo-Stoicism, exercised a strong influence on later moral thought. Born near Louvain, he spent most of his life in exile. At the age of twenty-four, he renounced the Catholicism of his native land, accepting the chair of his-

tory and eloquence at the Protestant University of Jena (1572). After two years, he returned—ostensibly as a repentant Catholic and loyal Brabantian. Again forced to flee—this time to the Calvinist Dutch—and abjuring Catholicism a second time, he accepted the chair of history at Leiden (1579). Harassed constantly by political and religious pressures, he went to the University of Louvain, becoming one of its most prominent scholars.

The vicissitudes of his life began during the time of civil war in the Low Countries. His *Tacitus* appeared at Louvain the year after his return from Jena (1575), as did his *Antiquae Lectiones*. These commentaries on Plautus signaled his adoption of a literary style modeled after Plautus, Tacitus, and Seneca. Lipsius was profoundly influenced by the thought and prose style of Seneca and devoted the remainder of his life to the study of Stoicism. This work of Lipsius, in turn, influenced Michel Eyquem de Montaigne, Guillaume du Vair, and Pierre Charron, and in England, Francis Bacon and Joseph Hall.

The victories of Don John of Austria (Gembloux, 1578) caused Lipsius to flee to the home of his friend Christophe Plantin, and then from Antwerp to Leiden, where he became a Calvinist. Here appeared *De Constantia* (1584), an introduction to Stoicism and his most famous work. Another well-known work, *Politicorum Libri Sex* (1589), led to a bitter dispute over its advocacy of severe methods to curb unrest. His position again became intolerable; finally, he made his peace with the Jesuits (and his old friend Martin Delrio) at Mainz (1591) and returned to Catholic Europe. He accepted the chair of history and Latin literature at Louvain (1592) and was also appointed professor of Latin at the Collegium Trilingue. He published several pieces on miracles as testimonials of faith, which added little to his fame. A projected *Fax Historica*, on Greco-Roman history and the histories of the Jews, Egyptians, and others, was never completed, although several parts were published. His last works were *Manuductio ad Stoicam Philosophiam* (1604), a miscellany of Stoic moral doctrines and survey of the *Paradoxa*; and *Physiologia Stoicorum*, a careful study of the Stoic logic and physics (1604). These make clear that Lipsius was responsible for a restored Stoic philosophy and particularly for the reemphasis on natural philosophy. Although he counted himself more an eclectic than an orthodox follower of any school, Lipsius attempted to show in these works that there was no real difficulty in reconciling the Stoic *fatum* with the Christian emphasis on free will (whereas in *De Constantia*, this possibility had been rejected).

## LITERATURE, PHILOSOPHY OF

The concepts of fiction and of literature are distinct. On the one hand, there are nonfictional literary works—essays, memoirs, biographies, histories, writings about nature, and even philosophy. Perhaps we should also include some letter collections, diaries, and journals. On the other, there are nonliterary fictions both within and apart from the world of art. Cinema is full of fictional stories. Paintings represent fictional scenes. Advertising, whatever the medium it employs, often presents us with fictions. However, the concepts of fiction and literature are intertwined.

The paradigmatic literary works have steadily drifted toward being exclusively works of fiction: novels, stories, poems, and plays. When David Hume wanted to make his mark as a man of letters, he chose history and philosophy as his media. By comparison, Jean Paul Sartre made his literary mark with novels and plays while establishing his reputation as a philosopher with the contemporary equivalent of treatises and inquiries. Does this shift in lit-

erature's center of gravity reflect something important about it? Is there something about the value of literature that makes fictional works most apt to contain such value or is there perhaps an overlap between the value of fiction and literary value? We will discuss both concepts here, beginning with philosophical issues concerning fiction.

## WHAT IS FICTION?

There are at least two senses of the word *fiction* that are easy to run together, but need to be distinguished for our present purpose. In one sense, a fiction can simply be a type of falsehood as when one says, "Your PhD is a fiction." By contrast, if one says that *Middlemarch* is a fiction, they are not saying that there is no such novel. They are saying that it is a certain type of book, story, or representation. It is true that there is such a book, story, or representation.

Unlike ambiguous words such as *bank*, there is probably some connection between the two senses of fiction, which explains the ease with which they are run together. Works of fiction typically contain an element of unreality. In reality, there is no such town as Middlemarch and no such people as the characters Dorothea or Casaubon who in the fiction inhabit the town. On another level, it is important to realize that the logical or semantic relationship between the two senses of fiction is loose. Fictions in the first sense can be lies and always involve falsehood. Works of fictions—a class of representations—are never lies, although they might just conceivably contain an intentional falsehood. They can refer to real things such as historical personages (Julius Caesar, Napoleon Bonaparte) and actual places (Rome, Moscow), and can contain truths about them.

The sense of fiction that primarily interests us is the second one, which refers to a class of works: works of fiction. Our job is to figure out what characterizes it and makes it distinct from other representations. Some have attempted to define fiction as a type of linguistic discourse. (Gale 1971, Urmson 1976). We know in advance that this is inadequate because of the ample existence of nonlinguistic fiction (see K. Walton [1990], for a survey and critique of this view). A second popular approach is to think of fiction as a form of pretense (though with no intent to deceive). This is on the right track, but the trick is to identify the right kind of pretense.

One might think that the standard function of a mode of representation such as language is to inform us about the actual world, to assert or show us things about it. Fiction could then be thought of as something derived from this standard use. Instead of actually asserting

something, a fictional story or its author pretends to assert it (Searle 1975). The problem with this version of the pretense view is that it is not always the right description of what artists are doing in their works. Consider a clear case of pretense: Someone is pretending to sing by lip-synching. They are doing one thing in order to pretend to do another. Is Eliot pretending to describe a real town by representing one that does not exist? That does not seem right. To adequately describe what Eliot is doing, it is enough to say that she is writing about an imaginary town. The problem is to say what *about* means in the previous sentence.

The make-believe view offers an answer (Walton 1990). In order to understand this view one has to recognize that make-believe is being used in a restricted, somewhat technical sense. Make-believe in the relevant sense involves two special features. First it involves props. Props are publicly accessible objects that guide imaginings. If, for example, children are playing school with dolls, the dolls are props. Second, make-believe, unlike some other imaginings, operates according to underlying rules about these props, which authorize or mandate certain imaginings. For example, the game of school might operate according to the rule that the number of students in the classroom is equal to the number of dolls arranged in a certain way.

According to the make-believe view, a work of fiction—whether it be a painting, novel, or poem—is a work that is intended or has the function of being a prop in a game of make-believe. What makes *Middlemarch* fictional is that it is a work—a novel in this case—intended to be or having the function of being a prop of the kind described above. It prescribes that we imagine certain things: that there is a town inhabited by such and such people. This is the sense in which it is *about* a town and its inhabitants.

The make-believe view has become one of the most widely held views about the nature of fiction (Currie 1990, Lamarque and Olsen 1994, Levinson 1996, Walton 1990), but it seems to count works as fictional items that are usually not so considered. Suppose that one writes an autobiography, but in such a way that the reader can vividly imagine the events of the writer's life. Then it appears that this work fulfills two functions. One is to inform the reader about the writer's life. A second is to enable the reader to engage in the kind of guided imagining that is constitutive of make-believe in the technical sense. Something similar happens in certain works of history and journalism, as well as nonfiction novels such as Truman Capote's *In Cold Blood*. All these works are props

that authorize certain imaginings. There are some who claim that because of this, these works are fictional even if the primary purpose lies elsewhere. (Walton 1990). But this is counterintuitive: Historical novels are fictional; history is not, even if it uses techniques that produce guided imaginings. How are we to express the difference?

It might be suggested that fiction always presents some things to the imagination that are placed there simply for the purpose of being imagined. Whether or not they express truths or refer to items in the actual world is irrelevant to their proper functioning in the work. This need not be true in the nonfiction works just mentioned. This does not mean that fictions cannot contain some elements that are meant to express truth, or pick out actual people, places, or other things. It just means that not everything in the fictional work so functions. Even in a historical novel, where every character picks out a real person from the past, we are to imagine certain doings or conversations without worrying whether they occurred. So on the present proposal, something is a fiction if it is a work that is intended for, or has the function of, being a prop in a game of make-believe, and at least some of the things it mandates to be imagined are placed in the work just for the sake of being imagined.

### FICTIONAL CHARACTERS

Works of fiction prescribe us to imagine people and their doings. Because of this, we say that such works, or their authors, create characters, about which we talk when describing and interpreting fictions. How should we understand such talk? How literally should we take it?

Consider the sentence, "Dorothea walked about the house with delightful emotion." A sentence such as this one normally refers to someone and says something about her, but if it appears in a work of fiction not about any actual personage, as this one does in *Middlemarch*, does it still refer to someone or, at least, to something? There are three answers to this question that currently have serious advocates: 1) the sentence still refers to someone, but a someone who does not exist; 2) the sentence does not refer to anyone, but it does refer to something (viz., a fictional character); 3) the sentence does not refer to anyone or anything.

Some proponents (Walton 1990, Lewis 1978) of the make-believe view hold the last view. Such a sentence refers to no one, but we make-believe that it does. In contrast, if we encounter in a work of fiction the sentence, "There was once a woman who was very happy," we may just make believe that there is some happy woman, at least until we are told more about her. An alternative way

of putting the third position is to say that, although the original sentence refers to nothing, it is fictionally true or true in the story that it does. (Adams, Stecker, Fuller 1997)

Proponents of the second view believe that such things as fictional characters actually exist. (Howell 1979, Lamarque and Olsen 1994, Thomasson 1999, van Inwagen 1977, Wolterstorff 1980). They posit such things more to explain the things we say about fiction than to explain fiction itself. They might even agree that the original sentence, as it occurs in the story, does not refer to anyone or anything. But in creating a work of fiction, we also create other things including characters. We can then go on to talk about them, compare them to other characters, quantify over characters, and so on. Consider the claim that Hamlet is one of the most enigmatic characters in literature. Here we appear to be saying something about Hamlet, not merely making believe something. Characters are not people, although fictional works speak of them as if they are.

The plausibility of this view hangs on whether we actually gain something by assuming fictional characters exist, that is denied to those who claim that we merely make-believe that people are being referred to in fictions, or who claim that it is merely true in the fiction, but not in reality, that such reference occurs. The latter would say that the enigmatic thing is what make believe the play *Hamlet* prescribes or what is true in the play. One thing that is gained by positing the existence of characters is a convenient way to express ourselves when we talk about fictions. The paraphrases of statements about characters in terms of what is true in a story or what make-believe is prescribed by a story will always be more cumbersome. In practice, we will always prefer character-talk. But that does not settle the question whether character-talk really refers to characters rather than works.

On the second view, characters are not what they appear to be. They are not princes, lovers, or detectives. They are not male or female. They are not people. Presumably they are abstract entities of some sort, the properties of which are all, in one way or another, parasitic on the properties of the works in which they appear. Dorothea has the property of being a character in *Middlemarch*. She, or rather it, also has the property of being ascribed the property of walking about with delightful emotion on a certain occasion. But Dorothea does not actually have the property of walking about with delightful emotion. Proponents of the first view find this counterintuitive. They claim that Dorothea is a person capable of ambulating, feeling emotion, and having a gender.

*Middlemarch* refers to her. In general, fictional works really do refer to people and other things, only often they are fictional people and other fictional things (i.e., people and things that do not exist) (Dilworth 2004, Parsons 1980, Zalta 1983, Zemach 1997). Dorothea and Hamlet do not exist, according to them. In this they agree with some of those who hold the make-believe view. But the people in this camp do not think that that is a reason to deny that we refer to fictional things. In fact, their chief claim is that we can refer to what does not exist including fictional people and places.

The straightforward way in which the first view treats characters is refreshing after the cumbersome paraphrases of the third view and the metaphysical abstractions of the second. Unsurprisingly, the straightforwardness comes with a cost: a highly unorthodox conception of reference. What is fair to call the majority view (which obviously does not mean it is the true one) is that one can only refer to what exists. When we refer to something, we pick it out, and what does not exist cannot be picked out because there is nothing to be picked out. If there were something, it would exist. The things we refer to are distinguished from others in virtue of their properties or characteristics, but nothing can have properties unless it exists in the first place. Existence is not just another property, but is the condition for having properties. What does (did, or will) not exist is nothing and so cannot have properties. If the first view is to get off the ground, it would have to show that the orthodox conception of reference is mistaken. Currently, there is no consensus about which of these views is the most plausible, but rather a lively, ongoing debate.

## THE PARADOX OF FICTION

Whatever is the correct view regarding fictional characters, once we become imaginatively involved in stories, we develop feelings and attitudes that appear to be directed toward creatures of fiction. We commonly say that we fear Dracula, despise Casaubon, or admire Sherlock Holmes. Yet there is something paradoxical about this. Feeling fear normally involves believing both that there is something to be feared, and that it poses a danger. We do not believe that Dracula actually exists, or that he poses a danger. Yet we feel fear nevertheless.

None of the views about fictional characters discussed in the preceding section offers a solution to this paradox. Two of the three deny that characters exist. They lead us into, rather than resolve, the problem. Those who claim fictional characters exist, deny that they are people, monsters, or anything else that could stir us to feel as we

do. Characters, on this view, are abstract entities, and fearing them would be akin to fearing the number five.

The paradox of fiction has provoked an enormous literature, and many proposed resolutions. Three will be discussed here. The first denies that the object of fear is really fictional. (Charlton 1984, Paskins 1977). When we say we despise Casaubon or admire Holmes, we mean that we despise or admire people like them. We despise self-absorbed people who care nothing even for those close to them. We admire people with intellects (but not necessarily opium addictions) such as Holmes. Factualism, as this view is sometimes called, has some truth to it, but it cannot solve the whole problem. We don't fear creatures such as Dracula because we have no more of a belief in vampires in general than we do in Dracula in particular. Equally important, many of the feelings we develop in the course of taking in a fictional work, are guided by the specific things we imagine as we do this, and for this reason do not generalize beyond the fiction. As Anna Karenina approaches the railroad station, we hope she will turn away rather than enter and throw herself under the train. This is not the hope that despairing lovers will turn away from train stations, or, more generally, will refrain from suicide.

A second view is a further development of the make-believe approach to fiction. (Walton 1990, Levinson 1996). The basic idea here is that fear of Dracula, for example, occurs within the game of the make-believe we play when watching a Dracula movie. Hence, it is not literally fear, any more than our thought that Dracula lives in Transylvania is literally a belief. Our make-believe may, nevertheless, be phenomenologically indistinguishable from fear. That is, it can involve the same physiological changes in the body, we can experience similar feelings, and we may have an attenuated desire to duck, hide, or flee. What we lack is the beliefs that we have with real fear, and the full range of desires and behavioral tendencies.

The last view, known as the thought theory, rebels at the idea that what we feel are not real emotions—for example, real fear. The chief claim here is that emotions such as fear and pity do not require a belief in the existence of the object of these emotions. The emotions can be caused by vivid imaginings as well (Carroll 1990, Dadlez 1997, Feagin 1996, Gron 1996, Lamarque 1996, Yanal 1999).

It is not clear that we need to take these last two views as offering genuinely distinct theories (Currie 1997). Proponents of the thought theory must admit that when imaginings cause fear, it is different in some important respects than belief-induced fear. In addition to the dif-

ference in propositional attitude (believing that versus imagining that) there are cognitive and behavioral differences as well. Proponents of the make-believe view are willing to admit we feel a real emotion, but deny it is literally fear or pity. So it is not clear that the argument between the make-believe view and the thought theory amounts to more than a dispute over the name we should give to the feelings that arise in our imaginative encounters with fiction. They appear to agree about the nature and cause of those feelings.

### WHAT IS LITERATURE?

The nature of literature is just as much a matter of controversy as the nature of fiction. However, it is now widely accepted that certain definitions will not work. In the first half of the twentieth century there was the hope that literature could be defined as a special way of using language. Literature uses defamiliarized language, drawing attention to its own literary devices. (Beardsley 1958, Jakobson 1960, Wellek and Warren 1973). But on the one hand, literary works can adopt the form of any kind of writing, from the scientific report to the advertising jingle. And on the other, all sorts of nonliterary uses of language can be rife with literary devices such as figures of speech, rhetorical techniques, implicit meanings, and so on.

Three proposals will be considered for defining literature. The first defines literature in terms of a role it plays in society or a community within society. Something is a work of literature, on this view, if it is a piece of writing that fulfills this role. Different theorists in this camp define the relevant role differently. For some, the relevant community is the community of critics, and the relevant role is that of being deemed worthy, or simply being the object, of critical attention (Fish 1980). For others, the relevant community is society at large, and the relevant role is sustaining the structure of power in the society (Eagleton 1983). It is not clear, however, that this approach can succeed in defining literature, whatever insights underlie it. Consider the first version. Who are the critics in question and what does critical attention consist in? They are the literary critics of course rather than the interpreters of philosophical texts (unless they are literary interpreters of those texts from the right academic departments). There are two dangers here and it is virtually impossible to avoid both. One danger is circular definition. The critics are those whose job it is to attend to a certain body of works—works of literature. Alternatively, the critics are those who use certain techniques—but those techniques can and sometimes are used on all

sorts of things so that we get the extension of literature quite wrong.

A second approach asserts literature is a practice. Writers, readers, critics all enter into this practice by attempting to create, enjoy, or facilitate the appreciation of literary aesthetic value (Lamarque and Olsen 1994). To avoid circularity, literary aesthetic value is cashed out as the value to be found in the experience of a subject or story that has a humanly interesting content in virtue of embodying one or more perennial themes and that is given a complex form suitable to developing such a theme.

What seems right about this approach is the claim that the creation of literature is imbedded in a social practice with distinctive aims, institutions, and traditions. What is controversial about the approach is its conception of the practice in terms of aiming at a single kind of value in a way that has remained unchanged, at least since ancient Greece. When one thinks of all the various items that are relatively uncontroversial examples of literature, from ancient classics to eighteenth century essays to contemporary poetry, one must wonder whether the formula proposed by this definition really encompasses all of literature.

An alternative is to think of literature as a practice defined by an evolving set of values or functions and central art forms. Currently, these forms are the novel, short story, drama, and poetry, and in addition to their aesthetic value, we also characteristically value them in other ways such as for fulfilling certain cognitive functions, and for providing opportunities for open-ended interpretation. Anything that belongs to such an art form and is seriously intended to provide one or another of these values is a work of literature, but so are other pieces of writing that fulfill these valuable functions to a significant degree whether or not they are in one of the central literary forms. Finally, it should be recognized that our current concept of literature has itself evolved from earlier predecessor concepts, such as those of fine writing (*belle lettres*) and the ancient Greek or Latin classic. Items that fall under these predecessor concepts also belong to literature by a principle of inclusion implicit in our current concept. (Stecker 1996).

### CRITICISM AND INTERPRETATION

Criticism is the blanket term for writing about or commenting on individual literary (or art) works. Being a blanket term, it covers different kinds of projects. One of the oldest kinds exists to orient an audience to new literary (artistic) productions as they appear. In doing this,

this kind of criticism fulfills a variety of distinct functions. It will typically identify the sort of work under discussion (e.g., an experimental novel in the manner of so and so), and acquaint a potential reader with important features of the work such as its style, plot, themes, and characters. Often implicit in these descriptions is an appreciative response (positive or negative) by the critic leading to an explicit evaluation of the work. The contemporary review is an example of this sort of criticism.

A different activity—that of analyzing and interpreting literary works—became a central critical activity in the twentieth century. This had a variety of causes. One was the rise of English and, more generally, literary studies, as an academic discipline. This generated a series of debates about the nature, content, value, and proper reception of such works, which associated a work with a great variety of ways of taking or reading it—in essence, a great variety of interpretations. Another factor was the growing prominence of difficult avant-garde works that are simply hard to understand. For such works at least, it is natural to turn to analysis and interpretation in order to understand and appreciate them. However, once we see how such analysis generates unexpected meanings or significance in these works, one suspects it might do so in any work, making any literary work a candidate for interpretation.

There are a variety of parameters along which approaches to interpreting literary works diverge. One that arose early on and has remained prominent concerns the significance of authorial intention in interpretation. Is the meaning of a work identical to such intentions, do they resolve ambiguities and other uncertainties in the work, or are they absolutely irrelevant to correctly interpreting it? Those who originally disagreed on this matter (Beardsley 1958 and 1970, Hirsch 1967) nevertheless did agree that the purpose of interpreting a work is to understand it better and that there is one best understanding that can in principle be attained. Notice there are two claims here: one about aim, one about number. These provide two further parameters about which literary theorists disagree.

Regarding the proper aim of interpretation, there are a variety of views. We have already mentioned one: understanding (Carroll 1992, Iseminger 1992, Juhl 1980, Margolis 1980, Stecker 2003). In some works, it is just difficult to grasp what is going on, and this can happen at all sorts of levels. A work can be hard to understand because of its historical or cultural distance from its audience. Alternatively, features of its style may make it difficult. There are poems where it is hard to understand what the

individual lines mean. There are novels and stories where it is hard simply to follow the plot. There are others where, while it is clear that a certain series of events have transpired, there are different ways in which one could understand their significance in the story. More commonly, one knows what happens in a story or what the lines of a poem say, but one does not grasp their point or the point of various bits. There are many other ways in which one may feel one's understanding of a work is inadequate, but in all such cases one turns to interpretations of a work for greater clarity.

An alternative to understanding as the aim of interpretation, is appreciation. (Davies 1982, Goldman 1990, Lamarque 2002). The point of interpretation on this view is to create ways of taking works that enhance their aesthetic value, or that guide the reader to an appreciative experience. Just whether, and precisely how, these two aims really differ is debatable: How can one lead a reader to an appreciative experience, without offering a way of understanding a work by organizing certain features of it around a theme, by describing a character as representing a type of person, identifying the point of a series of images, and so on? The difference may be in the way one evaluates interpretations. If one's aim is understanding, perhaps one hopes to get things right, to give a correct or true interpretation, whereas if one aims to enhance the value of the work or an experience of it, the test of an interpretation is in the aesthetic enjoyment it offers to readers.

Those who think the aim of interpretation is enhanced appreciation, also tend to be pluralists about the number of acceptable interpretations a work can bear. Interpretations that are considered acceptable within this camp range from those strictly constrained by conventions in place when the work was created (Davies 1996) to a virtual free play with a text (Barthes 1989). Among those who claim that the aim of interpretation is understanding, some, such as M. Beardsley and E.D. Hirsch, are monists arguing there is a single ultimately correct understanding of a work, whereas others are pluralists. A number of writers argue that meaning is relative to the constantly changing historical moment in which the work is received (Gadamer 1975, Margolis 1980), to the responses of readers in the face of textual indeterminacy (Iser 1980), or to the assumptions of critical communities (Fish 1980; Carrier 1991).

All such relativist views imply pluralism regarding correct understanding, although pluralism does not imply relativism. An alternative to relativism about a work's meaning is a pluralism about the acceptable aims

of interpretation (Stecker 1997 and 2003). Not all interpretation aims at recovering the meaning of a work. Some legitimately aims at enhancing appreciation, making a work significant to a contemporary audience, or to filling in indeterminacies in optional ways. These projects can clearly be pursued in a plurality of ways. By contrast if one's aim is to recover the intention with which the work was made, that may be a more monistic project. Perhaps, among these interpretive aims, there is one that attempts to identify a historically correct understanding of a work. There are currently a variety of proposals about what this might be (Carroll 2000, Levinson 1996, Stecker 2003).

### THE VALUE OF FICTION AND LITERATURE

At the beginning of this entry, we noted that, though fiction and literature are not the same thing, the paradigmatic literary forms today are all types of fiction: poetry, the novel, the short story, and the drama. The question we raised then and turn to now is what it is about the value of literature that makes fictional work the most typical to possess that value. Is it that the value of fiction and literature tend to overlap?

The philosophical debate about the value of literature might be aptly described as between those who answer this last question affirmatively and those who answer it negatively. Fiction, clearly, can serve all sorts of purposes, and we might value it for its function in almost any of these. The chief vehicle by which it achieves these valuable purposes is imaginative engagement (i.e., the make-believe that is intimately involved in the reception of fiction). Whether or not imaginative engagement is valuable in itself, it can quickly lead to things we clearly value (e.g., the pleasure of following a story and imaginatively participating in its world).

In addition to such pleasures, imaginative engagement can also be valuable in other ways. It is plausible that it can enhance valuable abilities: to make fine discriminations, to put ourselves in the shoes of others (to empathize), and to refine the ability to identify emotional and other psychological states. A fiction also might at least contribute to acquiring propositional knowledge. What is true in a fictional world is commonly at least possibly true in the actual world. Thus we can acquire knowledge of possibilities or conceptions of how things may be. A fiction may strongly suggest that something is not only possible, but that it actually is that way, and this may help us to learn about the way things not only might be, but are.

Clearly, all of these valuable traits of fiction can be possessed by literary works, fictional or not, but we can go further and say that literary fictions are the most likely to possess, in the highest degree, the cognitive values just mentioned. While not everyone would accept this, the more controversial issue concerns whether such traits add to the literary or artistic value of these works. A view that denies this claims instead that literary value resides wholly in the aesthetic experience a work offers, where this experience is fairly narrowly conceived. For example, one view that has been vigorously defended is that the aesthetic value of a work lies in its ability to create a complex form that explores a theme of perennial human interest (Lamarque and Olsen 1994). The appreciative experience, which determines the extent to which a work possesses aesthetic value, consists in following the development of the theme in the complex formal structure of the work. What is no part of the literary value is any insight the work might offer regarding the truth about the issues it explores.

This view has the virtue of serving as a corrective to the rejection of the relevance of the aesthetic, even suspicion about its place among the central human values, that has infected large swaths of literary theory (Eagleton 1983, Scholes 1978). However, even as an account of the aesthetic value of literature, it is far too narrow. For one thing, the perennial themes—fate, free will, nature versus nurture—just are not the organizing features of all literature. Some works are more concerned with characters, some with telling a riveting story, some with exhibiting an emotion, some with precise description, and so on. Perhaps we can say that every literary work offers a conception of some aspect of human experience, and when it is good literature, it does so in such a way that one can experience what it would be like if that conception were true (Stecker 1997). However, having said this, it becomes fairly obvious that it is perverse to deny that a further way that literature can be valuable is in the cognitive value of the conceptions offered. They can be valuable for getting it right, but also for suggesting new ways of thinking or experiencing, fruitful conjectures, as it were, even if they turn out to be ultimately wrong. After all we value philosophical works for just this reason, and there are many literary works that have overtly philosophical aims.

Just as fiction can be valuable in many ways, pluralism about literary value also seems to be the most sensible view. When literary works are evaluated not only for the aesthetic experience they offer, but the cognitive, ethical, art-historical value that they possess—to mention only some additional parameters that are relevant—we

are still evaluating them as literary works. Those who argue that interpretations of literary works should maximize the opportunities to appreciate them should welcome this point of view because it opens up so many new avenues from which such appreciation can develop.

## LITTRÉ, ÉMILE

(1801–1881)

Émile Littré, the French linguist and positivist philosopher, was born in Paris. From an early age Littré was interested in medicine and languages; and he received training in both. He is now best known for his *Dictionnaire de la langue française* (4 vols., Paris, 1863–1872) and his edition (with Charles Robin) of Pierre Hubert Nysten's *Dictionnaire de médecine, de chirurgie, de pharmacie, de l'art vétérinaire et des sciences qui s'y rapportent* (Paris, 1885). He was also prominent in radical political journalism (in *Le national* of Armand Carrel) and in freethinking circles. He became a member of the Académie des Inscriptions in 1838 and of the Académie Française in 1871, the latter over the violent objections of Bishop Dupanloup of Orléans. Littré was elected a deputy in 1871 and a senator for life in 1875.

These various activities and contacts enabled Littré to be unusually successful in his principal philosophical activity, the propagation of Auguste Comte's Positivism. He began to read Comte's *Cours de philosophie positive* in 1840, wrote a series of articles on it in *Le national* in 1844 and 1845 (published separately under the title *De la philosophie positive* in 1845 and later reprinted in his *Fragments de philosophie positive et de sociologie contemporaine* in Paris in 1876), and for a time became Comte's "principal disciple" and heir apparent as Director of Positivism and High Priest of the Religion of Humanity. Littré broke with Comte in 1852, however, over a combination of personal and political disagreements. Thereafter he took an increasingly independent line on Comte's doctrine as well, forming a loose group of disciples—distinct from the orthodox Comtian school—that found its principal expression in the journal *La philosophie positive*, started by Littré (with G. N. Vyrubov, the Russian positivist) in 1867. Littré himself contributed numerous important articles to the journal, but his position is stated most clearly in his *Auguste Comte et la philosophie positive* (Paris, 1863).

Littré's fundamental proposition was that during the 1840s, partly for personal reasons, Comte had abandoned

the positive method for the sake of a "subjective" method that vitiated all his subsequent work. Littré proposed to cleanse Positivism of the "aberrations" of Comte's "second career" by propagating the doctrine in the pure, scientific form of the *Cours*. He insisted that "there is only one stable point and that is science." Positivism as a scientific philosophy is in one aspect a system, "which comprehends everything that is known about the world, man, and societies," and in another aspect a method, "including within itself all the avenues by which these things have become known." It has, however, a practical purpose as well: to provide a "demonstrable rallying point" and a "definite direction" for humankind. Littré differed from Comte in doubting whether Positivism was yet sufficiently advanced to serve as a basis for social and political action. He also, among other things, denied ethics its place at the apex of the hierarchy of the sciences, which Comte in his later years had given it; for Littré, ethics was not an autonomous science at all. On the other hand, Littré was inclined, against Comte, to admit psychology as an independent discipline. Littré remained committed to the evolution of the positivist Religion of Humanity into a "spiritual power" but rejected Comte's prescriptions for its actual institutionalization.

Littré and his group often found it difficult to elaborate a consistent doctrine, largely because Comte's system had in fact been conceived as a unity very early in his career, and it was therefore wrong and illogical to divide his life and work in half.

**See also** Comte, Auguste; Positivism; Psychology.

### **Bibliography**

Littré's important works also include *Conservation, révolution et positivisme* (Paris, 1852; 2nd ed., 1879) and *La science au point de vue philosophique* (Paris, 1873).

For information on Littré, see É. Caro, *M. Littré et le positivisme* (Paris, 1883), which is hostile.

## LLOYD, GENEVIEVE

(1941–)

Born in Cootamundra in New South Wales, Australia, Genevieve Lloyd studied philosophy at the University of Sydney and then at Oxford. Her DPhil, awarded in 1973, was on Time and Tense. From 1967 until 1987 she lectured at the Australian National University, and it was during this period that she developed her most influential

ideas and wrote *The Man of Reason: "Male" and "Female" in Western Philosophy*, which was published in 1984. In 1987 she was appointed to the Chair of Philosophy at the University of New South Wales and was the first female professor of philosophy appointed in Australia.

Lloyd's contribution to feminist thought owes a good deal to Simone de Beauvoir. This is despite the fact that in *The Man of Reason* she is critical of Beauvoir's adoption of the pursuit of transcendence as the ideal of human excellence. Lloyd argues in this book that the historical notion of transcendence involves overcoming the body, which is represented as feminine, and so is a suspect value for women. At the same time her analysis of the symbolic meaning of philosophical concepts echoes Beauvoir. She follows Beauvoir in representing symbols as fundamentally dualistic, citing the Pythagorean table of opposites alluded to by Beauvoir in *The Second Sex*. Both agree that for the Pythagoreans, the male is associated with order and the right, light, and rational realm while the female corresponds to chaos and the left, dark, and irrational side of being. In an article published in *Australian Feminist Studies* in 1989, Lloyd explains that when Beauvoir speaks of woman as *other* she "is talking about the way culture has constructed the feminine—about its symbolic content" (p. 17). Likewise, Lloyd has been concerned with the ramifications of male power in the construction and control of symbolic structures. Unlike Beauvoir, however, she finds problematic the adoption by women of values traditionally symbolized as masculine. Yet she also shies away from a full endorsement of those strands of feminism of difference, which celebrate the body, emotion, and unreason as sources of essentially female values.

Though emphasizing the metaphorical association of reason with the male and reason's opposites and inferiors with the female, Lloyd is careful to avoid claiming that reason is *literally* male. In her concluding remarks to *The Man of Reason*, she says: "The claim that Reason is male need not at all involve sexual relativism about truth, or any suggestion that principles of logical thought valid for men do not hold also for female reasoners" (Lloyd 1984, p. 109). Nevertheless, she wants to avoid treating the maleness of reason as a *mere metaphor* that can easily be stripped away from the ideal of rationality. Alluding to Michèle Le Doeuff's (1948–) claim that the metaphors and images used by philosophers constitute a philosophical imaginary of marginalized tropes integral to the commitments of a text, she undermines the distinction between the literal and metaphorical. Elsewhere she evokes Jacques Derrida's deconstruction of the philosophical distinction between literal truth and metaphori-

cal embellishment. However, Lloyd has not developed a detailed analysis of the relationship between metaphor, literal truth, rational argument, and literary effect, and this lends a certain obscurity to her position.

Despite having inspired Lloyd's line of argument, Le Doeuff has been critical of Lloyd's analysis of Francis Bacon's metaphors, arguing that the association between reason and masculinity discussed by Lloyd and found in the twentieth-century translation of Bacon is not to be found in Bacon's Latin original. She suggests in *The Sex of Knowing* that in general, historical claims that women are irrational are (false) literal claims intended to undermine women's intellectual authority.

Lloyd argues that Cartesian dualism is particularly problematic for feminism, and in her edited collection *Feminism and History of Philosophy*, sums up this suspicion. "What made the Cartesian philosophy suspect for feminists was its association with the doctrine of dualism—the rigid separation of minds and bodies as utterly distinct kinds of being. The dichotomy came to be seen as reinforcing the denigration of women, in association with the body, in opposition to the ideal of reason associated with "male 'transcendence'" (Lloyd 2000, p. 9). In her later work, Lloyd urges the fruitfulness for feminism of Benedict de Spinoza's treatment of the mind as an idea of the body, which she interprets as an ontological doctrine that undermines the polarities of the Cartesian tradition. During the 1990s she turned to working on Spinoza and published a number of books on his thought.

It is nevertheless questionable whether Cartesian dualism is literally a suspect metaphysical doctrine for feminists or whether Spinoza's form of monism would serve women better. Feminist historians such as Margaret Atherton (1943–) and Hilda Smith (1941–) have argued that historically, dualism has favored feminism. Even prior to René Descartes, women such as Christine de Pizan (1365–1431) were able to point to the immateriality of the soul as evidence that women's souls were the same as men's and so women were men's spiritual equals. Moreover, Descartes's method, with its reliance on reason and clear and distinct ideas, was accessible to women who had not had a university education. Descartes was not himself a misogynist; he took seriously the arguments of his correspondent the Princess Elizabeth of Bohemia (1630–1714), and his philosophy ushered in a period during which significant numbers of women engaged with the new philosophy.

The impact the perennial but by no means universal association between the mind and a masculine master ought to have on one's views concerning the literal mate-

riality of the soul remains obscure. Lloyd's seminal critique of the rhetoric of the male philosophical tradition has been widely influential. The consequences that one should draw from that critique, and its significance for feminism and metaphysics, remain contested.

## LOCKE, JOHN (1632–1704)

John Locke, English empiricist and moral and political philosopher, was born in Wrington, Somerset. Locke's father, an attorney and for a time a clerk to the justices of the peace in Somerset, fought on the parliamentary side in the first rebellion against Charles I. Locke was reared in a liberal Puritan family and early learned the virtues of temperance, simplicity, and aversion to display. Though his father was severe and remote from him in early youth, as Locke matured they became close friends.

In 1646 Locke entered Westminster School, where he studied the classics, Hebrew, and Arabic. Little time was given at Westminster to science and other studies, and its harsh discipline, rote learning, and excessive emphasis on grammar and languages were later condemned by Locke.

In 1652 Locke was elected to a studentship at Christ's Church, Oxford. He received his BA in 1656 and remained in residence for the master's degree. He was not happy with the study of Scholastic philosophy and managed to inform himself of many new areas of thought. As a master, Locke lectured in Latin and Greek and in 1664 was appointed censor of moral philosophy.

His father's death in 1661 left Locke with a small inheritance and some independence. During these years he became acquainted with many men who were to have a profound influence upon his life. From Robert Boyle, Locke learned about the new sciences and the corpuscular theory, as well as the experimental and empirical methods. Confronted with the choice of taking holy orders, continuing as a don, or entering another faculty, Locke chose medicine. Though well trained, he never practiced medicine, nor was he permitted to take the medical degree, which would have permitted him to teach the profession, until 1674, although in 1667 he began to collaborate with the great physician Thomas Sydenham.

In 1665 Locke was sent on a diplomatic mission accompanying Sir Walter Vane to the elector of Brandenburg at Cleves. He subsequently rejected a secretaryship under the earl of Sandwich, ambassador to Spain, and returned to Oxford. It was at this time that his interests began to turn seriously to philosophy. Descartes was the first philosopher whom Locke enjoyed reading and the first to show him the possibility of viable alternatives to the Schoolmen.

Locke had met Lord Ashley, earl of Shaftesbury, in 1662 at Oxford. They found much pleasure in each other's company, and the astute Shaftesbury quickly recognized Locke's talents. In 1667 he invited Locke to live

with him in London as his personal physician. Later Locke served him well in many other capacities. Under Shaftesbury Locke found himself in the center of the political and practical affairs of the day. He assisted Shaftesbury in the framing of a constitution for the colony of Carolina. For a time he was secretary for the presentation of benefices and then secretary to the Council of Trade and Plantations. Locke was always at home in the world of practical affairs, and many of his philosophical attitudes reflect this interest. At the same time he became a fellow in the Royal Society, where he continued to be in touch with learning.

Locke, never robust in health, in 1675 went on a prolonged visit to France, where he made many friends and came into contact with the foremost minds of his day. His studies and criticisms of Descartes were deepened under the influence of various Gassendists.

In 1679 Locke returned to an England torn by intense political conflicts. Shaftesbury, who had become the leader of the parliamentary opposition to the Stuarts, alternated between political power and impotence. The close association with Shaftesbury brought Locke under suspicion; he was kept under surveillance. Shaftesbury was tried for treason in 1681, but acquitted. He subsequently fled England for Holland, where he died in 1683. Locke, at Oxford, uncertain of his position and fearing persecution, also fled England, arriving in Holland in September 1683. The king had demanded that Locke be deprived of his studentship at Oxford, and news of this demand caused Locke to prolong his stay. After the death of Charles II and the ascension of James II to the throne, the duke of Monmouth attempted a rebellion, which failed. Locke was denounced as a traitor, and the crown demanded of the Dutch that he be returned to England. No great effort was made to comply with the demand, and Locke remained in Holland.

During his stay in Holland, Locke again acquired a wide circle of distinguished friends and wrote extensively. He contributed an article as well as reviews to the *Bibliothèque universelle* of Jean Leclerc; these were his first published works. He wrote in Latin the *Epistola de Tolerantia*, which was published anonymously in 1689 and translated as the *First Letter concerning Toleration*. He also worked assiduously on *An Essay concerning Human Understanding*, which he had been writing off and on since 1671. In 1688 the *Bibliothèque universelle* published an abstract of the *Essay*.

These activities did not prevent him from being deeply engaged in politics. The plot to set William of Orange on the throne of England was well advanced in

1687, and Locke was, at the very least, advising William in some capacity. The revolution was accomplished in the fall of 1688, and in February 1689 Locke returned to England, escorting the princess of Orange, who later became Queen Mary.

In 1689 and 1690 Locke's two most important works, *An Essay concerning Human Understanding* and *Two Treatises of Government*, were published. From 1689 to 1691 Locke shuttled between London and Oates, the home of Sir Francis and Lady Masham, the daughter of Ralph Cudworth. He had declined an ambassadorial post only to accept a position as commissioner on the Board of Trade and Plantations. Apparently his practical wisdom was invaluable, for when he wished in 1697 to resign because of ill health, he was not permitted to do so. He remained until 1700, serving when he could, although his health was extremely poor.

In 1691 Locke made Oates his permanent residence at the invitation of Lady Masham. It was, for the aging Locke, a place of refuge and joy; there he received visits from Newton, Samuel Clarke, and others. These were productive years for Locke. *Some Thoughts concerning Education* appeared in 1693. The second edition of *Essay* was published in 1694. In the following year *The Reasonableness of Christianity* was published anonymously. He answered criticism of it in *A Vindication of the Reasonableness of Christianity* (London, 1695) and in a second *Vindication* in 1697. From 1697 to 1699 Locke engaged in an epistolary controversy with Edward Stillingfleet, bishop of Worcester.

However, Locke's health steadily failed him. After 1700, when the fourth edition of *Essay* appeared, he remained almost constantly at Oates. He was engaged in editing *Two Treatises of Government*, for no edition which pleased him had yet appeared. In his last years he wrote extensive commentaries on the epistles of St. Paul, which were published posthumously. On October 28, 1704, while Lady Masham was reading the Psalms to him, Locke died. Lady Masham wrote of him, "His death was like his life, truly pious, yet natural, easy and unaffected."

**CHARACTER.** The Lovelace Collection of Locke's personal papers in the Bodleian Library, Oxford, shows that Locke's character and personality were more complex than had been suspected. The great affection and respect which so many men and women had for him are testimony to his charm and wisdom. That he was modest, prudent, pious, witty, and eminently practical was long known. But he was also extremely secretive and apparently given to excessive suspicion and fears. When his life-

long friend, James Tyrrell, voiced his suspicion that Locke had written *Two Treatises*, Locke was evasive and would not admit the fact. When he suspected that Tyrrell was spreading the report that Locke was the author, Locke angrily demanded an explanation. At the same time, Locke showed great affection for many friends and a real fondness for children. In maturity he could not abide religious intolerance or suffer tyranny. He was passionately devoted to truth and strove constantly to state the truth as he saw it, but always with a caution that distrusted all dialectic, even his own, when it appeared to go beyond common sense.

**INFLUENCES ON LOCKE.** Locke's philosophy is grounded in medieval thought, though he, like Descartes, turned away from it as far as possible. The Cambridge Platonists, notably Ralph Cudworth and Benjamin Whichcote, influenced him greatly with respect to religious tolerance, empirical inquiry, and the theory of knowledge. Locke was indebted to Richard Hooker in his political thought. Hobbes probably influenced him somewhat, though Locke was concerned not to be classed as a Hobbiist. The two most important philosophical influences upon him were Descartes and Pierre Gassendi. From Descartes he learned much that is incorporated in *Essay*, and in Gassendi and the Gassendists he found support to challenge the doctrine of innate ideas and the radical rationalistic realism of Descartes. Gassendi helped to convince Locke both that knowledge begins in sensation and that intellect, or reason, is essential to the attainment of truth and knowledge.

### AN ESSAY CONCERNING HUMAN UNDERSTANDING

Locke's position in the history of Western thought rests upon *An Essay concerning Human Understanding* and *Two Treatises of Government*. He spent long years working out the thought of each, and he carefully and lovingly revised and corrected them for subsequent editions. Locke wrote two drafts of his *Essay* in 1671, and in 1685 he wrote a third. The first edition, though dated 1690, appeared in late 1689. During the years between 1671 and 1689, Locke revised and reorganized many of his original concepts. In response to criticisms of the first edition of *Essay*, he introduced a number of changes in subsequent editions. This long period of gestation and Locke's subsequent modifications of his initial public statement disclose primarily the refinement and clarification of his philosophy by way of certain important additions, but never by a radical or fundamental departure from his basic position.

From the first appearance of *An Essay concerning Human Understanding* Locke was criticized for being inconsistent in his theory of knowledge, vague in the presentation and development of many of his ideas, and wanting in thoroughness in developing other ideas. But these criticisms have in no way diminished either the importance or the influence of *Essay* on subsequent thinkers. By no means the first of the British empiricists, Locke nonetheless gave empiricism its firmest roots in British soil, where it still proudly flourishes. It must be remembered that Locke was also a rationalist, though one of quite different orientation from such Continental thinkers as Descartes, Spinoza, and Malebranche. In Locke many strands of traditional thought are rewoven into a new fabric. Subsequent thinkers, notably Berkeley, Hume, and Kant, perhaps fashioned more coherent and consistent systems, but it is doubtful whether they were more adequate to what Locke might have called the plain facts.
